Introduction

The A10 Thunder® Application Delivery Controller (ADC) is a high-performance solution designed to accelerate and optimize critical applications, ensuring their reliable and efficient delivery.

This document assists you in deploying Thunder® ADC instances on AWS Cloud using CloudFormation Templates (CFT).

The following steps provide a high-level overview of the deployment process:

1. Provision the AWS Cloud network infrastructure.

There are custom templates available for creating new virtual private cloud for same or different availability zone, network security groups (NSGs), subnets, and elastic public IP to provision the new infrastructure. The creation of these resources is optional; if the resources already exist, they can be reused.

For more information, see [Create Elastic Public IP](#), [Create Virtual Private Cloud](#), and [Create Virtual Private Cloud for Different Availability Zones](#).

For more information on other prerequisites, see [Prerequisites](#).

2. Create Thunder virtual machine/s on the AWS Cloud.

There are custom templates available for creating virtual machines (VMs) along with network interface card (NIC) settings on AWS Cloud with built-in Thunder.

For more information on the various deployment templates, see [Deployment Templates](#).

You can deploy Thunder on the AWS Cloud using AWS Management Console.

3. Configure Thunder.

There are custom Python scripts available to apply the new Thunder configurations. Different scripts are available for various configuration needs.

For more information, see [ADC Configuration Templates](#).

Terminology

The following is a glossary of AWS terms commonly used in this document:

- **Access control list (ACL)** — A firewall or a security layer on the subnet level. For more information, see <https://docs.aws.amazon.com/AmazonS3/latest/userguide/acls.html>
- **AWS Management Console** — A web console to create and monitor AWS resources. For more information, see <https://aws.amazon.com/console/>
- **AWS Command Line Interface (CLI)** — An interface that can be launched to start a CLI session. The interface can be launched using one of the following:
 - **Linux shells** — Use programs such as [bash](#), [zsh](#), and [tcsch](#) to run commands in Linux or macOS.
 - **Windows command line** — Use Windows command prompt or PowerShell to run commands in Windows.
 - **Remotely** — Use Amazon Elastic Compute Cloud (Amazon EC2) instances through a remote terminal program such as MobaXterm, [PuTTY](#), [SSH](#), or with AWS Systems Manager to run commands in AWS. For more information, see http://docs.aws.amazon.com/cli/index.html?nc2=h_ql_doc_cli.
- **Autoscaling Group (ASG)** — A feature that enables automatic scaling of the number of instances (virtual servers or machines) in response to varying demand for applications or services.
- **AWS Access Keys** — The credentials for an IAM user or the AWS account root user.
- **CloudWatch** — A service that allows you to monitor various elements of your AWS account. For more information, see <https://docs.aws.amazon.com/cloudwatch/index.html>.
- **Global Server Load Balancing (GSLB)** — A process to distribute incoming network traffic across multiple servers or data centers located in different geographical locations.
- **Health Probe** — A health probe is used to determine the health status of the virtual machine instances in the backend pool.
- **High Availability (HA)** — A capability to remain operational and accessible for a significantly high percentage of the time.

- **Hybrid Cloud** — A cloud computing model that combines private cloud and public cloud services within the same seamless infrastructure.
- **Lambda** — A serverless computing that will replace Elastic Compute Cloud (EC2) instances, for most of the functionality of EC2. For more information, see <https://docs.aws.amazon.com/lambda/latest/dg/welcome.html>
- **Network security group (NSG)** — A network security group (NSG) contains a list of security rules that allow or deny network traffic to resources connected to AWS virtual networks (VNet). The NSGs can be associated with subnets or individual NICs attached to the VMs. When an NSG is associated with a subnet, the rules apply to all the resources connected to the subnet.
- **Python3** — The latest major version of the Python programming language.
- **Security group (SG)** — The firewall or security layer on the server or instance level. For more information, see <https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/ec2-security-groups.html>.
- **Subnet** — A subsection of a network that generally includes all the computers in a specific location. For more information, see <https://docs.aws.amazon.com/AWSCloudFormation/latest/UserGuide/aws-resource-ec2-subnet.html>
- **Virtual Private Cloud (VPC)** — A private subsection of AWS that you can control and in which you can place AWS resources. For more information, see <https://docs.aws.amazon.com/vpc/latest/userguide/what-is-amazon-vpc.html>
- **vThunder** — An A10 Thunder instance for virtual machine.

Prerequisites

To create and configure Thunder virtual machine on the AWS cloud using CFT templates, you must ensure that the following prerequisites are met:

1. Download A10 CFT Templates from [GitHub](#).
2. Ensure that you have an AWS account with sufficient permissible role. For more information, see [Security Policy for AWS User](#).
3. Access [AWS Management Console](#) to create Thunder virtual machine using CFT templates.

4. Sign up [here](#) to get Thunder Trial license.
5. Install Python on your machine to execute the ADC Thunder configuration scripts. For more information, see [Install Python3](#).
6. Create the access keys (*access key ID* and *secret access key*) if you don't have them already. For more information, see <https://docs.aws.amazon.com/powershell/latest/userguide/pstools-appendix-sign-up.html>
7. Create an SSH key from **AWS Management Console > EC2 Formation > Key Pairs > Create key pair** with the following:
 - **Name:** *<your key name>*
 - **Key pair type:** RSA
 - **Private key file format:** .pem

Save this SSH key for future use. For more information, see <https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/create-key-pairs.html>

For any queries, reach out to [A10 Networks Support](#).

Image Repository

[Table 1](#) provides the list of ACOS versions and modules that support the CFT templates:

Table 1 : Supported ACOS versions

ACOS Version	ADC	CGN	SSLi	TPS
64-bit Advanced Core OS (ACOS) version 6.0.4	√	X	X	X
64-bit Advanced Core OS (ACOS) version 6.0.3	√	X	X	X
64-bit Advanced Core OS (ACOS) version 6.0.2	√	X	X	X
64-bit Advanced Core OS (ACOS) version 6.0.1	√	X	X	X
64-bit Advanced Core OS	√	X	X	X

Table 1 : Supported ACOS versions

ACOS Version	ADC	CGN	SSLi	TPS
(ACOS) version 6.0.0-P2-SP1				
64-bit Advanced Core OS (ACOS) version 6.0.0-P1	√	X	X	X
64-bit Advanced Core OS (ACOS) version 5.2.1-P8	√	X	X	X
64-bit Advanced Core OS (ACOS) version 5.2.1-P7	√	X	X	X
64-bit Advanced Core OS (ACOS) version 5.2.1-P6	√	X	X	X

Deployment Templates

This section helps you in provisioning a new Thunder virtual machine on the AWS cloud.

Before proceeding, it is recommended to review the [Prerequisites](#).

To provision a new virtual Thunder ADC instance on an AWS cloud, perform the following steps:

1. [Create Virtual Private Cloud/Create Virtual Private Cloud for Different Availability Zones](#)
It is not mandatory to create new resources, the existing resources can be used in deployment and configuration.
2. [Create Elastic Public IP](#).
It is not mandatory to create new resource, the existing resource can be used in deployment and configuration. Some deployment templates require Elastic Public IP.
3. Select an appropriate template for deploying vThunder ADC on AWS cloud according to your use case.

[Table 2](#) provides a list of various use cases along with their respective supported CFT templates.

Table 2 : Supported CFT Templates

Use Case	Template Name	Number of Thunder/s	Number of NICs	Data-in NIC VIP	Description
Standalone Thunder ADC	Thunder-2NIC-1VM	1	2	Private	<ul style="list-style-type: none">• Creates one vThunder instance with one management and one data NIC (data-in), see Figure 1.

Table 2 : Supported CFT Templates

Use Case	Template Name	Number of Thunder/s	Number of NICs	Data-in NIC VIP	Description
					<ul style="list-style-type: none"> • Applies additional configuration on vThunder as required: <ul style="list-style-type: none"> ◦ Change Password ◦ A10 License ◦ SSL Certificate ◦ Basic Server Load Balancer ◦ Backend Server Autoscaling
Thunder ADC in High Availability mode with Private/Public VIP	Thunder-3NIC-2VM	2	3	Private or Public	<ul style="list-style-type: none"> • Creates two vThunder instances with HA setup and each vThunder has one management and two data NICs (data-in and data-out), see Figure 6. • Configures data-in

					Cloud GSLB

After completing the deployment process, proceed to configure your setup. For more information, see [ADC Configuration Templates](#).

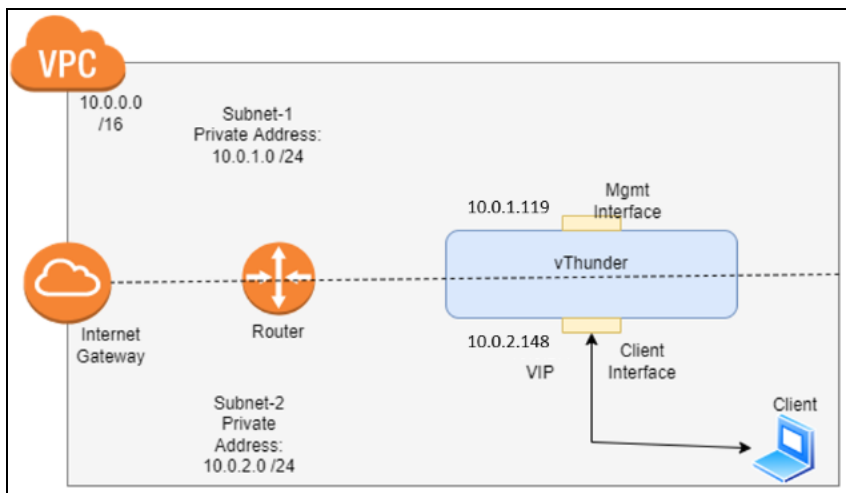

Thunder-2NIC-1VM

This template creates a new virtual machine with pre-loaded Thunder instance and creates two new network interface cards (NICs).

For more information, see [Create Thunder Virtual Machine](#).

NOTE: Use a suitable VM size that supports at least two NICs. For VM sizes, see [List of Supported Instance Types](#).

Figure 1 : Standalone Thunder ADC

Additional Thunder configurations are available that can be applied as needed:

- [Change Password](#)
- [A10 License](#)
- [SSL Certificate](#)
- [Basic Server Load Balancer](#)
- [Backend Server Autoscaling](#)

Various templates are available for different deployment needs.

For more information, see [Deployment Templates](#).

The following topics are covered:

Create Thunder Virtual Machine	23
Configure Thunder	28
Verify Deployment	29
Verify Traffic Flow	33

Create Thunder Virtual Machine

The A10-vThunder-2NIC-1VM template is used to create a Thunder virtual machine with two network interface cards.

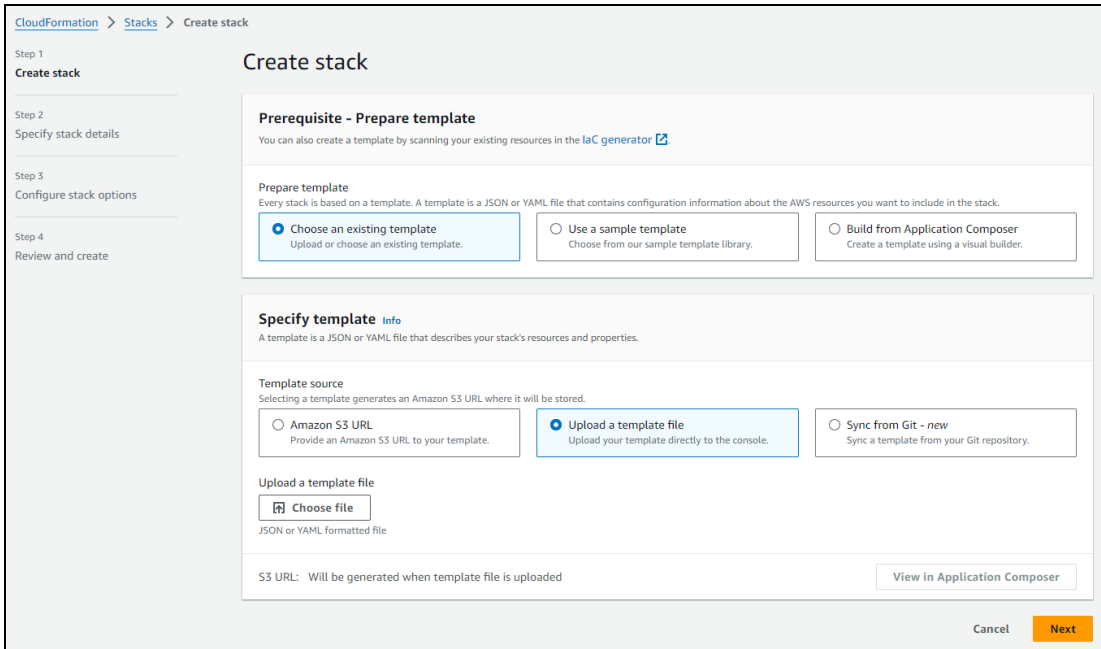

Before deploying this template, it is recommended to review the [Prerequisites](#).

To create the Thunder virtual machines using A10-vThunder-2NIC-1VM template, perform the following steps:

1. Download **A10-vThunder_CFT-TEMPLATES > A10-vThunder-2NIC-1VM** template from [GitHub](#).
2. Download [A10-vThunder-2NIC-1VM](#) template.
3. From AWS Management Console, navigate to **CloudFormation > Stacks > Create Stack > With new resources (standard)**.

The Create stack window is displayed.

Figure 2 : Create stack window

- In the **Prerequisite - Prepare template** section, select **Choose an existing template**.

After selecting this option, the Specify template section is displayed.

- In the **Specify template** section, select **Upload a template file** and click **Choose file** to browse and upload the following template file from the downloaded CFT folder:

CFT_TMPL_2NIC_1VM.json

The selected template file name is displayed as the chosen file.

NOTE: This template contains pre-populated default values that can be modified as required. It does not create a new Elastic IP, security groups, subnets, and Virtual Private Network.

- Click **Next**.

The **Specify stack details** window is displayed.

Figure 3 : Specify stack details window

7. In the **Specify stack details** window, enter or select the following:

Table 3 : JSON Parameters

Resource Name	Description
Stack name	<p>Specify a stack name containing letters (A-Z and a-z), numbers (0-9), and dashes (-).</p> <p>Here, the stack name is provided as <code>vth-2nic-1vm</code>.</p>
AMIID	<p>Specify the AMI ID of the required A10 vThunder image. By default, A10 Thunder ADC for Advanced Load Balancing - BYOL AMI ID is set for us-east-1 region.</p> <p>To get the AMI ID, go to the AWS Management Console > EC2 > Launch instance > Application and OS Images (Amazon Machine Image) > search for the relevant vThunder image and then copy the AMI ID.</p> <p>For more information on the available Thunder images with different capacities under respective regions, see List of ACOS AMI ID.</p>
AllocationIdEIP	Specify an allocation ID of the required elastic IP.

Table 3 : JSON Parameters

Resource Name	Description
	To get the allocation ID, go to the AWS Management Console > EC2 > Elastic IPs > <i><elastic_IP_address></i> > Summary and then copy the Allocation ID .
CustomTagName	Specify the custom tag name. The custom tag key is added to all the resources created using the CFT template. This tag is used to track the cost of resources in the AWS Cost Explorer.
CustomTagValue	Specify the custom tag value. The custom tag key is added to all the resources created using the CFT template. This tag is used to track the cost of resources in the AWS Cost Explorer. The default custom tag value is a10-vthunder-adc .
EC2Instance	Select an instance/compute type supported for vThunder from the available list. By default, instance type is m4.xlarge which contains 4 vCPU and 16 GiB memory. The minimum requirement for vThunder is 4 vCPU and 16 GiB memory. For more information on product pricing, see AWS Marketplace . If the required instance type is not available in the list, go to AWS Management Console > EC2 > Launch instance > Find and copy the relevant instance type in the template. For more information, see Supported Instance Types .
KeyPair	Select a keypair from the available list. A key pair is a set of security credentials which consist of a public key and a private key. This keypair is used to verify your identity when connecting to an Amazon EC2 instance.
SecurityGroupData	Select the required security group ID from the available list for data interface within the selected

Table 3 : JSON Parameters

Resource Name	Description
	Virtual Private Network.
SecurityGroupMgmt	Select the required security group ID from the available list for the management interface within the selected Virtual Private Network.
SubnetDataID	Select the required subnet ID from the available list for the data traffic flow inward and outward to vThunder within the selected Virtual Private Network.
SubnetMgmtID	Select the required subnet ID from the available list for management interface of the vThunder within the selected Virtual Private Network.
Tenancy	Select the required tenancy from the available list. Tenancy defines the distribution of EC2 instances across the physical hardware that affects pricing. It specifies if the Amazon EC2 instance is hosted on shared or single-tenant hardware.
VPC	Select the required Virtual Private Network ID to configure vThunder.
Zone	Select a zone from the existing availability zones. AWS offers a range of options for managing availability and resiliency for your applications. NOTE: Make use of the replicated VMs across the availability zones to protect your applications and data against the data center outages and maintenance events.

8. Click **Next**.

The **Configure stack options** window is displayed.

9. Verify the other fields and change the values appropriately. (Optional)

10. Click **Next**.

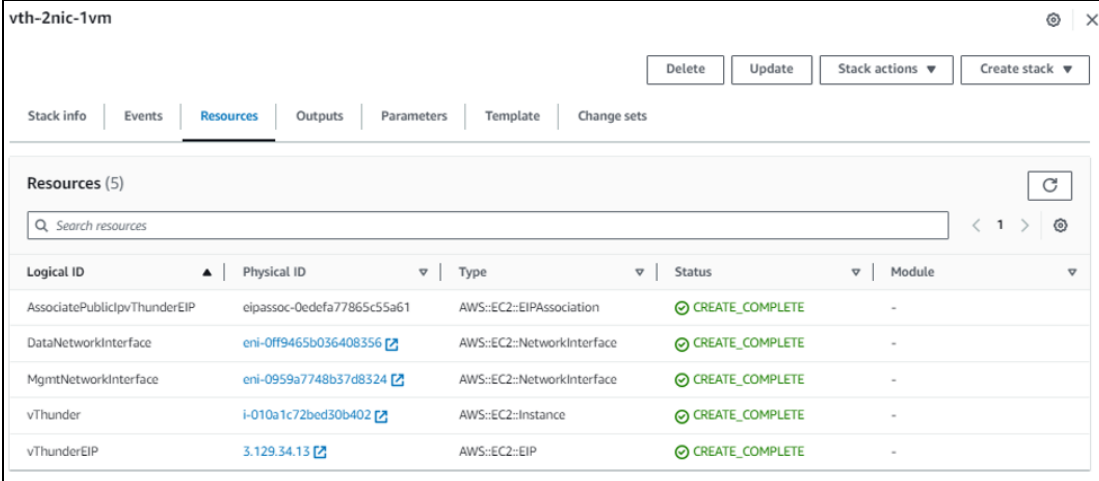

The **Review** <stack_name> window is displayed.

- Verify if all the stack configurations are correct and then click **Submit**.

NOTE: The system may take a few minutes to create the resources and display the stack status as **CREATE_COMPLETE**.

- Verify if the elastic IPs are created in the **AWS Management Console** > **CloudFormation** > **Stacks** > `<stack_name>` > **Resources** tab.

- [Create Client Machine.](#)

Configure Thunder

The following configurations can be applied to the deployed vThunder instance depending on your use case and requirement, see [Deployment Templates](#):

- [Change Password](#)
- [A10 License](#)
- [SSL Certificate](#)
- [Basic Server Load Balancer](#)
- [Backend Server Autoscaling](#)

Verify Deployment

To verify vThunder SLB deployment using CFT, perform the following steps:

1. Access the vThunder instance using CLI.
2. Run the following command to verify the running configuration:

```
vThunder(config) (NOLICENSE) #show running-config
```

If the deployment is successful with basic SLB, HTTP template, and Persist-cookie template configuration, the following output is displayed:

```
!  
interface ethernet 1  
  enable  
  ip address dhcp  
!  
!  
slb server server1 10.0.2.8  
  port 53 udp  
  port 80 tcp  
  port 443 tcp  
!  
slb service-group sg443 tcp  
  member server1 443  
!  
slb service-group sg53 udp  
  member server1 53  
!  
slb service-group sg80 tcp  
  member server1 80  
!  
slb template persist cookie persist-cookie  
  expire 60  
  encrypt-level 0  
  name a10-cookies  
  match-type service-group  
!  
slb template http hostname-test
```

```
    host-switching contains s1 service-group sg80
!
slb template http url-test
    url-switching regex-match s1 service-group sg80
!
slb virtual-server vip 10.0.2.148
    port 53 udp
        source-nat auto
        service-group sg53
    port 80 http
        source-nat auto
        service-group sg80
        template http url-test
        template persist cookie persist-cookie
    port 443 https
        source-nat auto
        service-group sg443
        template http url-test
        template persist cookie persist-cookie
!
!
end
```

If the deployment is successful with SLB on Backend Autoscale, HTTP template, and Persist-cookie template configuration, the following output is displayed:

```
!
interface ethernet 1
    enable
    ip address dhcp
!
!
slb server i-0177b3b4899596316 10.0.2.8
    port 53 udp
    port 80 tcp
    port 443 tcp
!
slb service-group sg443 tcp
```

```
    member i-0177b3b4899596316 443

    port 80 http
        source-nat auto
        service-group sg80
        template http url-test
        template persist cookie persist-cookie
    port 443 https
        source-nat auto
        service-group sg443
        template http url-test
        template persist cookie persist-cookie
!
!
end
```

3. Run the following command to verify the SSL configuration:

```
vThunder(config) (NOLICENSE) #show pki cert
```

If the deployment is successful, the following SSL configuration is displayed:

Name	Type	Expiration	Status

server certificate		Jan 28 12:00:00 2028 GMT	[Unexpired, Bound]

4. Run the following command on the vThunder instance to verify GLM configuration:

```
vThunder(config) #show license-info
```

If the GLM is successfully applied on vThunder, the following GLM configuration is displayed:

```

Host ID      : XXXXXXXXC264BECCCFEXXXXXXXXXXXXXXXXXXX
USB ID      : Not Available
Billing Serials: A10XXXXecbe0000

```

Verify Traffic Flow

To verify the traffic flow from client machine to server machine via vThunder, perform the following:

1. From **AWS Management Console**, navigate to **EC2 > Instances**.
2. Select the vThunder instance name and then click the **Networking** tab.

Here, `vth-inst1` is the vThunder instance name.

- Note down the IP address of the data subnet under the Private IPv4 address. Here, 10.0.2.148 is the data subnet value.

Figure 5 : vThunder instance

- Select your client instance from the **Instances** list.
Here, `client1` is the client instance name.
- Click **Connect**.
A **Connect to instance** window with **EC2 Instance Connect** tab is displayed.
- Click **Connect**.
A **Terminal** window is displayed.
- Replace the IP address of the data subnet noted above in the following command and then run the command in the Terminal window to send the traffic from the client machine:

```
curl <vThunder_instance_data-nic_private_ip>
```
- Verify if a response is received from client server (For example: Apache Index page).
- SSH your client machine and run the following command to verify the HTTP template traffic flow:

```
curl <vThunder_instance_data-nic_private_ip>:<port_number>/<host-match-string or url-match-string>/
```

Example

```
curl 10.0.2.148:80/s1/
```

Verify if a response is received from client server (For example: Apache Index page).

10. SSH your client machine and run the following commands to verify the Persist cookie template traffic flow:

- a. Verify the current cookie configuration:

```
curl --head <vThunder_instance_data-nic_private_ip>
```

- b. Run the following commands to save the cookies in the `cookie.txt` file:

```
curl -b cookie.txt -c cookie.txt <vThunder_instance_data-nic_private_ip>  
cat cookie.txt
```

Example

```
curl --head 10.0.2.148  
curl -b cookie.txt -c cookie.txt 10.0.2.148  
cat cookie.txt
```

11. Run the following command on the vThunder instance to view the persistence load-balancing statistics:

```
vThunder(config)#show slb persist
```

If the deployment is successful, the following summary persistence statistics is displayed:

	Total

URL hash persist (pri)	0
URL hash persist (sec)	0
URL hash persist fail	0
SRC IP persist ok	0
SRC IP persist fail	0
SRC IP hash persist(pri)	0
SRC IP hash persist(sec)	0
SRC IP hash persist fail	0
DST IP persist ok	0
DST IP persist fail	0
DST IP hash persist(pri)	0
DST IP hash persist(sec)	0
DST IP hash persist fail	0
SSL SID persist ok	0
SSL SID persist fail	0
Cookie persist ok	1
Cookie persist fail	0
Persist cookie not found	2
Persist cookie Pass-thru	0
Enforce higher priority	0

If the Persist-cookie configuration is successful, a value is displayed for the **Cookie persist ok** parameter, else the value is 0.

Thunder-3NIC-2VM

This template creates two vThunder instances in the same or different availability zone with HA setup and each vThunder has one management and two data NICs (data-in and data-out). It configures data-in network interface card (NIC) with Private VIP or Public VIP. It also provides feature to do the AWS HA failover using Private IP as Alien IP.

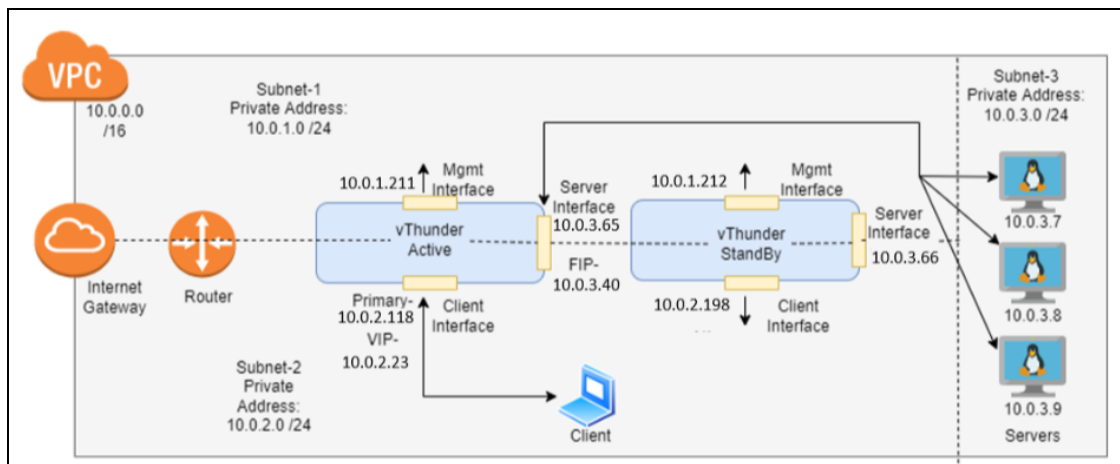

NOTE: Use a suitable VM size that supports at least three NICs. For VM sizes, see [List of Supported Instance Types](#).

High Availability within same Availability Zone

To create two vThunder instances in the same availability zone with HA setup, see [Create Thunder Virtual Machines for Same Availability Zone](#).

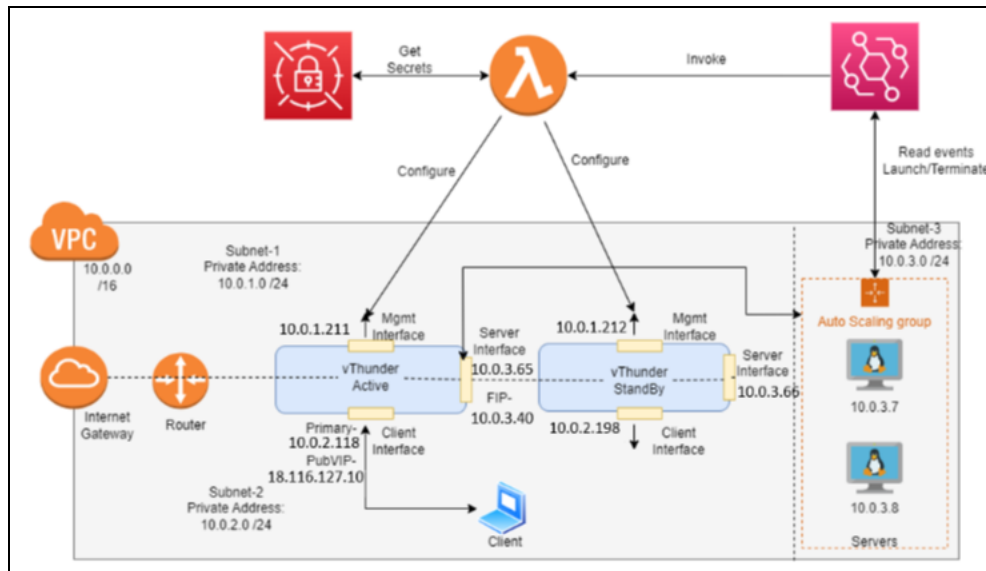

The following figure shows SLB Thunder ADC in High Availability mode with Private VIP:

Figure 6 : Thunder-3NIC-2VM with Private VIP

The following figure shows SLB Thunder ADC in High Availability mode with Public VIP:

Figure 7 : Thunder-3NIC-2VM with Public VIP

The following additional Thunder configurations are available that can be applied as needed:

- [Change Password](#)
- [A10 License](#)
- [SSL Certificate](#)
- [Basic Server Load Balancer](#)
- [Backend Server Autoscaling](#)
- [High Availability](#)

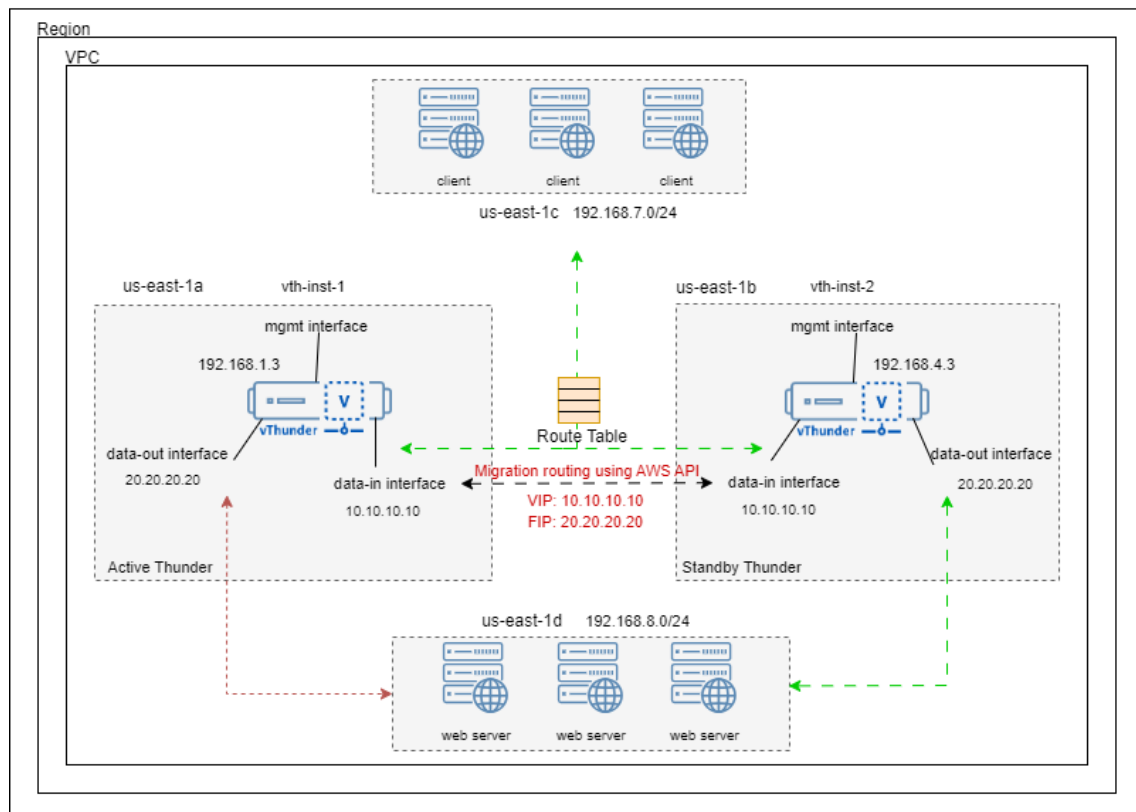

High Availability across different Availability Zones

The HA Across AZs only supports IPv4 and shared partitions with two Thunder devices at a time. It does not support more than two Thunder devices with multiple partitions.

To create two vThunder instances across different availability zones with HA setup, see [Create Thunder Virtual Machines for Different Availability Zones](#).

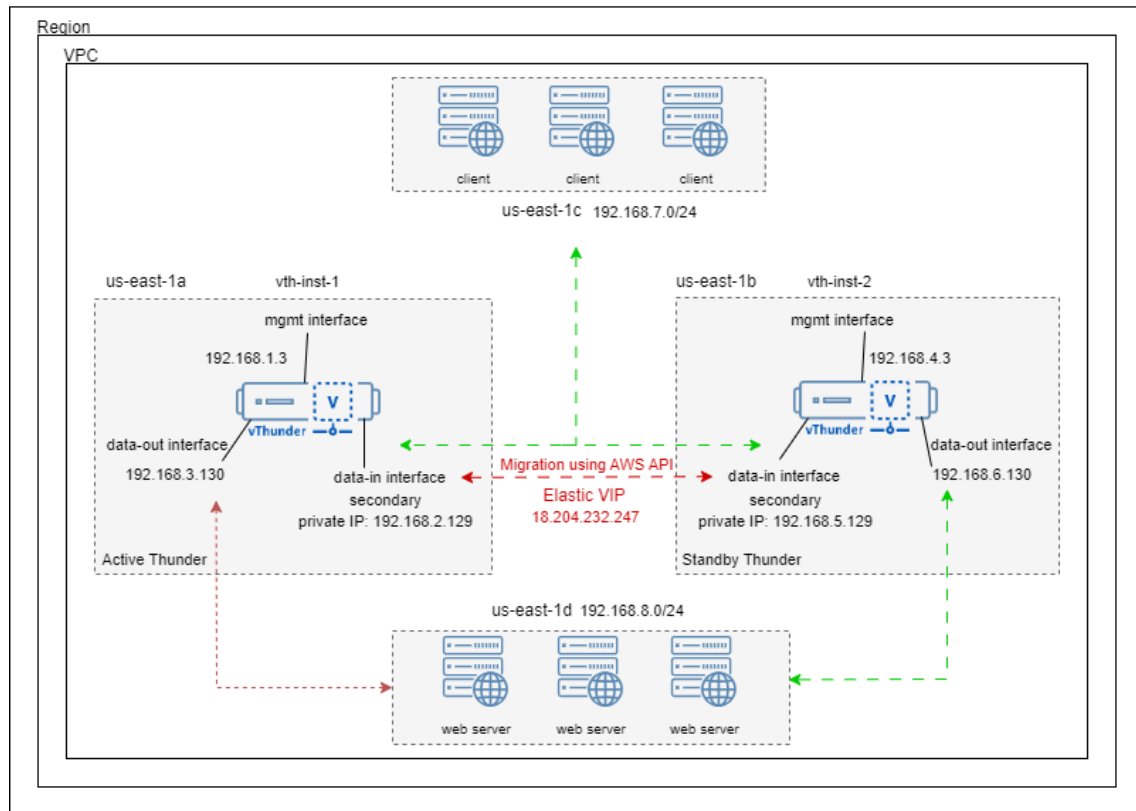

The following figure shows AWS HA using Private IP as Alien IP (Traffic from same VPC):

Figure 8 : Thunder-3NIC-2VM with Private VIP

The following figure shows AWS HA using Elastic IP (Traffic from internet):

Figure 9 : Thunder-3NIC-2VM with Public VIP

The following additional Thunder configurations are available that can be applied as needed:

- [Change Password](#)
- [A10 License](#)
- [SSL Certificate](#)
- [Basic Server Load Balancer](#)
- [Backend Server Autoscaling](#)
- [High Availability Across Availability Zones](#)

Various templates are available for different deployment needs.

For more information, see [Deployment Templates](#).

The following topics are covered:

Create Thunder Virtual Machines for Same Availability Zone	41
Create Thunder Virtual Machines for Different Availability Zones	63

Create Thunder Virtual Machines for Same Availability Zone

The A10-vThunder-3NIC-2VM template is used to create two Thunder virtual machines in same availability zone with three network interface cards each and configure the data-in network interface card with Private VIP or Public VIP.

Before deploying this template, it is recommended to review the [Prerequisites](#).

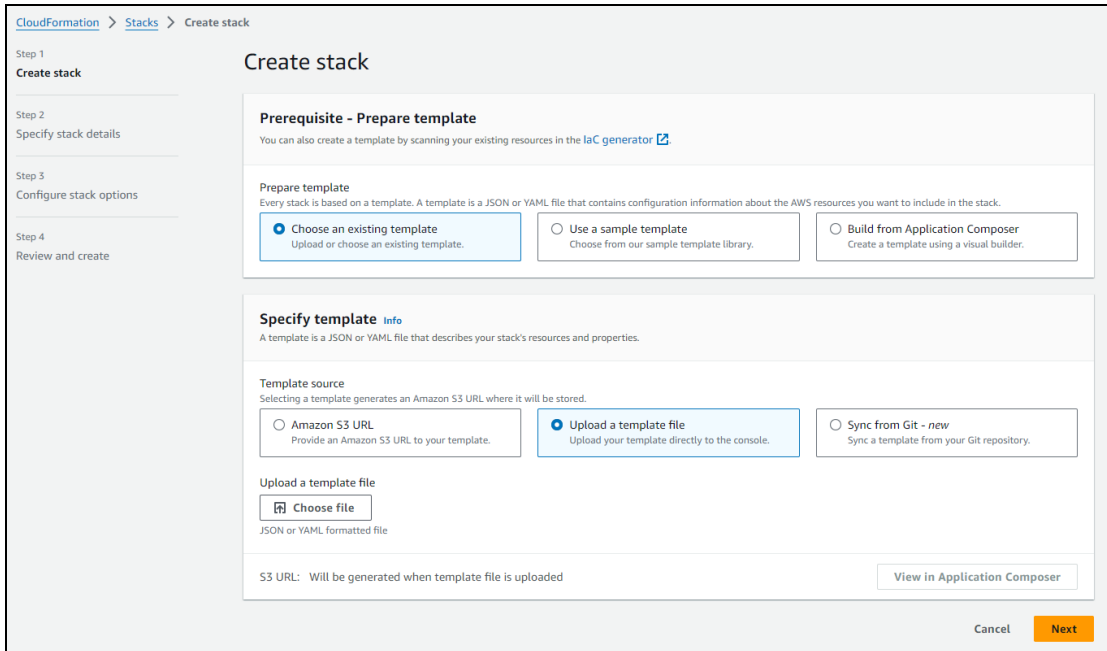

NOTE: vThunder instances should have the same versions; otherwise, traffic flow will be disrupted.

To create the Thunder virtual machines in same availability zones using A10-vThunder-3NIC-2VM template, perform the following steps:

1. Download **A10-vThunder_CFT-TEMPLATES > A10-vThunder-3NIC-2VM** template from [GitHub](#).
2. From AWS Management Console, navigate to **CloudFormation > Stacks > Create Stack > With new resources (standard)**.

The Create stack window is displayed.

Figure 10 : Create stack window

3. In the **Prerequisite - Prepare template** section, select **Choose an existing template**.

After selecting this option, the Specify template section is displayed.

4. In the **Specify template** section, select **Upload a template file** and click **Choose file** to browse and upload the following template file from the downloaded CFT folder:

CFT_TMPL_3NIC_2VM.json

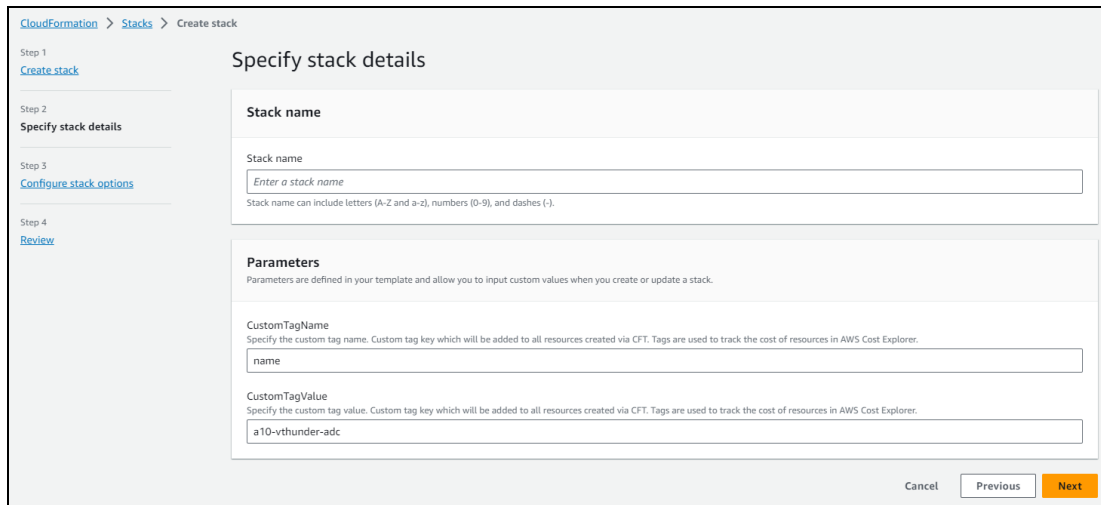

The selected template file name is displayed as the chosen file.

NOTE: This template contains pre-populated default values that can be modified as required. It does not create a new primary private IP address, virtual private IP address, security groups, subnets, and virtual private network.

5. Click **Next**.

The **Specify stack details** window is displayed.

Figure 11 : Specify stack details window

6. In the **Specify stack details** window, enter or select the following:

Table 4 : JSON Parameters

Resource Name	Description
Stack name	Specify a stack name containing letters (A-Z and a-z), numbers (0-9), and dashes (-). Here, the stack name is provided as <code>vth-3nic-2vm</code> .
AMIID	Specify the AMI ID of the required A10 vThunder image. By default, A10 Thunder ADC for Advanced Load Balancing - BYOL AMI ID is set for us-east-1 region. To get the AMI ID, go to the AWS Management Console > EC2 > Launch instance > Application and OS Images (Amazon Machine Image) > search for the relevant vThunder image and then copy the AMI ID. For more information on the available Thunder images with different capacities under respective regions, see List of ACOS AMI ID .
AllocationIdEIPActive	Specify an allocation ID of the required active elastic IP.

Table 4 : JSON Parameters

Resource Name	Description
	<p>This elastic IP address is the management public IP address of the Thunder instance 1.</p> <p>To get the allocation ID, go to the AWS Management Console > EC2 > Elastic IPs > <elastic_IP_address> > Summary and then copy the Allocation ID.</p>
AllocationIdEIPStandBy	<p>Specify an allocation ID of the required standby elastic IP.</p> <p>This elastic IP address is the management public IP address of the Thunder instance 2.</p> <p>To get the allocation ID, go to the AWS Management Console > EC2 > Elastic IPs > <elastic_IP_address> > Summary and then copy the Allocation ID.</p>
CreatePubVIP	Select Yes if VIP is a public IP address or select No if VIP is a private IP address.
CustomTagName	Specify the custom tag name. The custom tag key is added to all the resources created using the CFT template. This tag is used to track the cost of resources in the AWS Cost Explorer.
CustomTagValue	<p>Specify the custom tag value. The custom tag key is added to all the resources created using the CFT template. This tag is used to track the cost of resources in the AWS Cost Explorer.</p> <p>The default custom tag value is a10-vthunder-adc.</p>
EC2Instance	Select an instance/compute type supported for vThunder from the available list. By default, instance type is m4.xlarge which contains 4 vCPU and 16 GiB memory. The minimum requirement for vThunder is 4 vCPU and 16 GiB memory. For more information on product pricing, see AWS

Table 4 : JSON Parameters

Resource Name	Description
	<p>Marketplace.</p> <p>If the required instance type is not available in the list, go to AWS Management Console > EC2 > Launch instance > Find and copy the relevant instance type in the template. For more information, see Supported Instance Types.</p>
KeyPair	Select a keypair from the available list. A key pair is a set of security credentials which consist of a public key and a private key. This keypair is used to verify your identity when connecting to an Amazon EC2 instance.
PrimaryPrivateIP	Specify the primary private IP address from data-in subnet CIDR. This IP address is the primary private IP address of the Thunder instance 1.
SeconddayPrivateIP	Specify the secondary private IP address from data-in subnet CIDR. This IP address is the virtual private IP (VIP) address of the Thunder instance 1.
SecurityGroupData	Select the required security group ID from the available list for data interface within the selected Virtual Private Network.
SecurityGroupMgmt	Select the required security group ID from the available list for the management interface within the selected Virtual Private Network.
SubnetDataINID	Select the required subnet ID from the available list for the data traffic flow inward to vThunder within the selected Virtual Private Network.
SubnetDataOutID	Select the required subnet ID from the available list for the data traffic flow outward from vThunder within the selected Virtual Private Network.
SubnetMgmtID	Select the required subnet ID from the available list for managing vThunder within the selected Virtual Private Network.

Table 4 : JSON Parameters

Resource Name	Description
Tenancy	Select the required tenancy from the available list. Tenancy defines the distribution of EC2 instances across the physical hardware that affects pricing. It specifies if the Amazon EC2 instance is hosted on shared or single-tenant hardware.
VPC	Select the required Virtual Private Network ID to configure vThunder.
Zone	Select a zone from the existing availability zones. AWS offers a range of options for managing availability and resiliency for your applications. NOTE: Make use of the replicated VMs across the availability zones to protect your applications and data against the data center outages and maintenance events.

- Click **Next**.

The **Configure stack options** window is displayed.

- Verify the other fields and change the values appropriately. (Optional)
- Click **Next**.

The **Review** *<stack_name>* window is displayed.

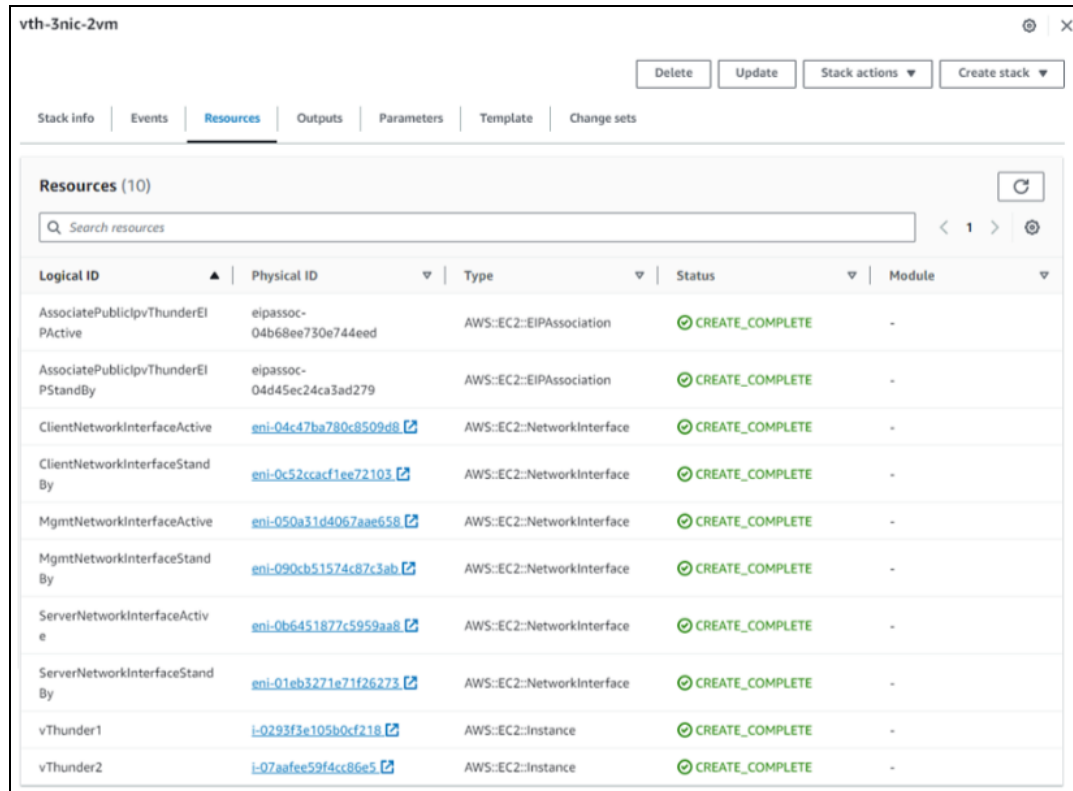

- Verify if all the stack configurations are correct and then click **Submit**.

NOTE: The system may take a few minutes to create the resources and display the stack status as **CREATE_COMPLETE**.

- Verify if the elastic IPs are created in the **AWS Management Console** > **CloudFormation** > **Stacks** > *<stack_name>* > **Resources** tab:

- Data-in network interface card with Private IP

12. [Access Thunder Virtual Machine.](#)
13. [Create Server Machine.](#)
14. [Create Client Machine.](#)

Configure Thunder

The following configurations can be applied to the deployed vThunder instance depending on your use case and requirement, see [Deployment Templates](#):

- [Change Password](#)
- [A10 License](#)
- [SSL Certificate](#)
- [Basic Server Load Balancer](#)
- [Backend Server Autoscaling](#)
- [High Availability](#)

Verify Deployment

To verify vThunder SLB deployment using CFT, perform the following steps:

1. Access the vThunder instances using CLI.
2. Run the following command on vThunder instance 1:

```
vThunder-Active(config)#show running-config
```

If the deployment is successful with basic SLB, HTTP template, and Persist-cookie template configuration, the following output is displayed:

```
!Current configuration: 349 bytes

```

3. Run the following command on vThunder instance 1:

```
vThunder-Active (config) #show pki cert
```

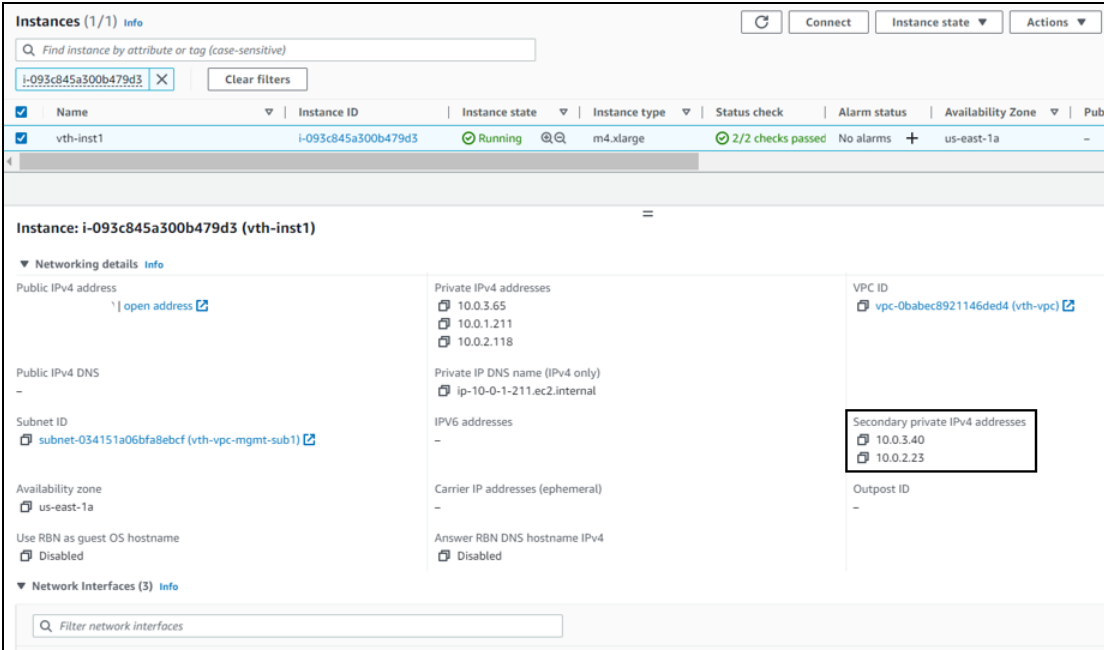

If the deployment is successful, the following SSL configuration is displayed:

```
Name      Type      Expiration  Status
-----
server certificate Jan 28 12:00:00 2028 GMT [Unexpired, Bound]
```

At this point, the vThunder instance 2 has the following prompt:

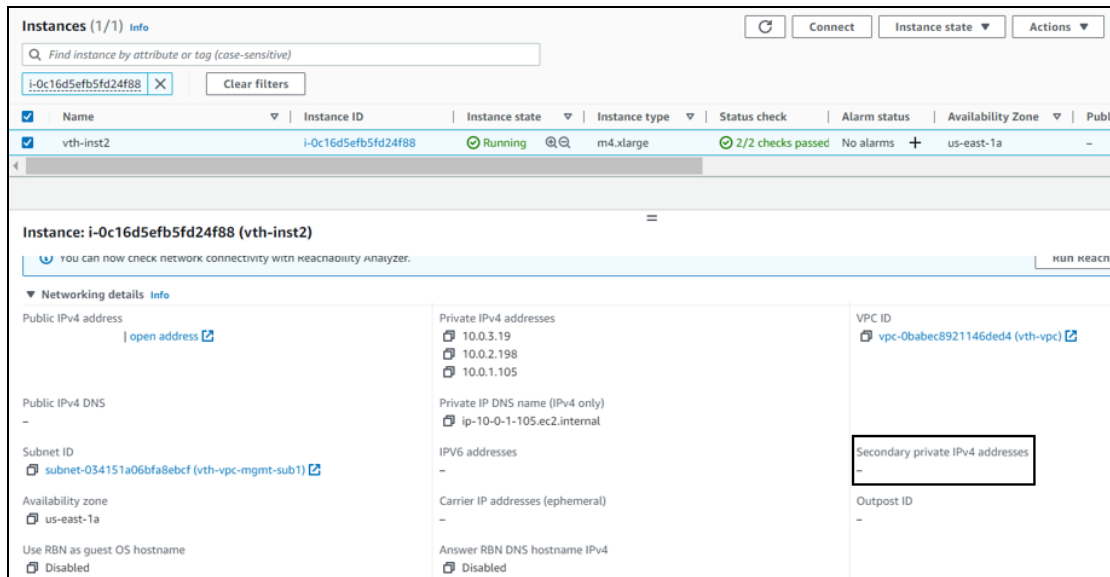

```
vThunder-Standby (config) #
```

Figure 14 : vThunder instance 1 - Active

The screenshot displays the AWS Management Console interface for an EC2 instance named 'vth-inst1'. The instance is in a 'Running' state with a '2/2 checks passed' status. The 'Networking details' section is expanded, showing various network configurations. A red box highlights the 'Secondary private IPv4 addresses' section, which lists two addresses: 10.0.3.40 and 10.0.2.23. Other visible details include the instance ID (i-093c845a300b479d3), instance type (m4.xlarge), VPC ID (vpc-0babec8921146ded4), and availability zone (us-east-1a).

Figure 15 : vThunder instance 2 - Standby

4. Run the following command on vThunder instance 1:

```
vThunder-Active(config)#vrrp-a force-self-standby enable
vThunder-Active(config)#
vThunder-ForcedStandby(config)#
```

At this point, IP switching occurs and the vThunder instance 2 prompt becomes:

```
vThunder-Active(config)#
```

5. Run the following command on vThunder instance 2:

```
vThunder-Active(config)#show running-config
```

If the deployment is successful, the following SLB configuration is displayed:

```

vth-inst2	i-0c16d5efb5fd24f88	Running	m4.xlarge	2/2 checks passed	No alarms	us-east-1a	-

Instance: i-0c16d5efb5fd24f88 (vth-inst2)

Details | Security | **Networking** | Storage | Status checks | Monitoring | Tags

You can now check network connectivity with Reachability Analyzer.

Networking details Info

Public IPv4 address open address	Private IPv4 addresses 10.0.3.19 10.0.2.198 10.0.1.105	VPC ID vpc-0babc8921146ded4 (vth-vpc)
Public IPv4 DNS -	Private IP DNS name (IPv4 only) ip-10-0-1-105.ec2.internal	Secondary private IPv4 addresses 10.0.3.40 10.0.2.23
Subnet ID subnet-034151a06bfa8ebcf (vth-vpc-mgmt-sub1)	IPv6 addresses -	Outpost ID -
Availability zone us-east-1a	Carrier IP addresses (ephemeral) -	
Use RBN as guest OS hostname Disabled	Answer RBN DNS hostname IPv4 Disabled	

Network Interfaces (3) Info

- If you want to make vThunder instance 1 active, run the following command on vThunder instance 1:

```
vThunder-ForcedStandby(config) #vrrp-a force-self-standby disable
```

At this point, IP switching occurs and the vThunder instance 1 prompt becomes:

```
vThunder-Active (config) #
```

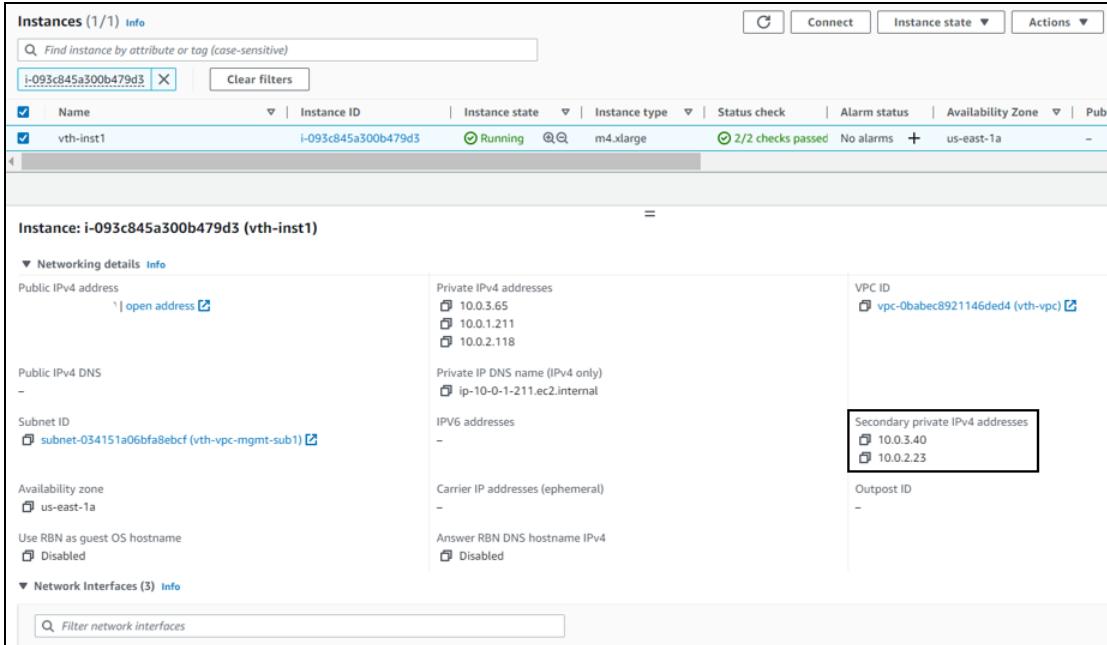

NOTE: If you want to access the vThunder instances using GUI, re-login the instances using the new admin user password and NOT the *EC2 Instance ID*.

Verify Traffic Flow

To verify the traffic flow from client machine to server machine via vThunder, perform the following:

1. From **AWS Management Console**, navigate to **EC2 > Instances**.
2. Select the active vThunder instance name and then click the **Networking** tab.
3. Note down the Data-In Subnet VIP address of the active vThunder instance.

Figure 18 : vThunder instance 1

The screenshot displays the AWS Management Console interface for an EC2 instance named 'vth-inst1' with Instance ID 'i-093c845a300b479d3'. The instance is in a 'Running' state. The 'Networking details' section is expanded, showing the following information:

- Public IPv4 address:** (Link to open address)
- Public IPv4 DNS:** -
- Subnet ID:** subnet-034151a06bfa8ebcf (vth-vpc-mgmt-sub1)
- Availability zone:** us-east-1a
- Use RBN as guest OS hostname:** Disabled
- Private IPv4 addresses:** 10.0.3.65, 10.0.1.211, 10.0.2.118
- Private IP DNS name (IPv4 only):** ip-10-0-1-211.ec2.internal
- IPv6 addresses:** -
- Carrier IP addresses (ephemeral):** -
- Answer RBN DNS hostname IPv4:** Disabled
- VPC ID:** vpc-0babc8921146ded4 (vth-vpc)
- Secondary private IPv4 addresses:** 10.0.3.40, 10.0.2.23 (highlighted with a red box)
- Outpost ID:** -

4. Select your client instance from the **Instances** list. Here, `vth-client` is the client instance name.
5. Click **Connect**. A **Connect to instance** window with **EC2 Instance Connect** tab is displayed.

6. Click **Connect**.
A **Terminal** window is displayed.
7. Replace the Data-In Subnet VIP address of the active vThunder instance noted above in the following command and then run the command in the Terminal window to send the traffic from the client machine:

```
curl <vThunder_instance_datain-nic_secondary_private_or_public_ip_vip>
```

Example for Private VIP

```
curl 10.0.2.23
```

Example for Public VIP

```
curl 18.116.127.10
```

8. Verify if a response is received.
9. SSH your client machine and run the following command to verify the HTTP template traffic flow:

```
curl <vThunder_instance_datain-nic_secondary_private_or_public_ip_vip>:<port_number>/<host-match-string or url-match-string>/
```

Example for Private VIP

```
curl 10.0.2.23:80/s1/
```

Example for Public VIP

```
curl 18.116.127.10:80/s1/
```

Verify if a response is received from client server (For example: Apache Index page).

10. SSH your client machine and run the following commands to verify the Persist cookie template traffic flow:
 - a. Verify the current cookie configuration:

```
curl --head <vThunder_instance_datain-nic_private_or_public_ip_vip>
```

- b. Run the following commands to save the cookies in the `cookie.txt` file:

```
curl -b cookie.txt -c cookie.txt <vThunder_instance_datain-nic_private_or_public_ip_vip>  
cat cookie.txt
```

Example for Private VIP

```
curl --head 10.0.2.23
curl -b cookie.txt -c cookie.txt 10.0.2.23
cat cookie.txt
```

Example for Public VIP

```
curl --head 18.116.127.10
curl -b cookie.txt -c cookie.txt 18.116.127.10
cat cookie.txt
```

11. Run the following command on the active vThunder instance to view the persistence load-balancing statistics:

```
vThunder(config)#show slb persist
```

If the deployment is successful, the following summary persistence statistics is displayed:

	Total

URL hash persist (pri)	0
URL hash persist (sec)	0
URL hash persist fail	0
SRC IP persist ok	0
SRC IP persist fail	0
SRC IP hash persist(pri)	0
SRC IP hash persist(sec)	0
SRC IP hash persist fail	0
DST IP persist ok	0
DST IP persist fail	0
DST IP hash persist(pri)	0
DST IP hash persist(sec)	0
DST IP hash persist fail	0
SSL SID persist ok	0
SSL SID persist fail	0
Cookie persist ok	1
Cookie persist fail	0
Persist cookie not found	2
Persist cookie Pass-thru	0
Enforce higher priority	0

If the Persist-cookie configuration is successful, a value is displayed for the `Cookie persist ok` else the value is 0.

Create Thunder Virtual Machines for Different Availability Zones

The A10-vThunder-3NIC-2VM template is used to create two Thunder virtual machines across different availability zones with three network interface cards each and configure the data-in network interface card with Private VIP or Public VIP.

Before deploying this template, it is recommended to review the [Prerequisites](#).

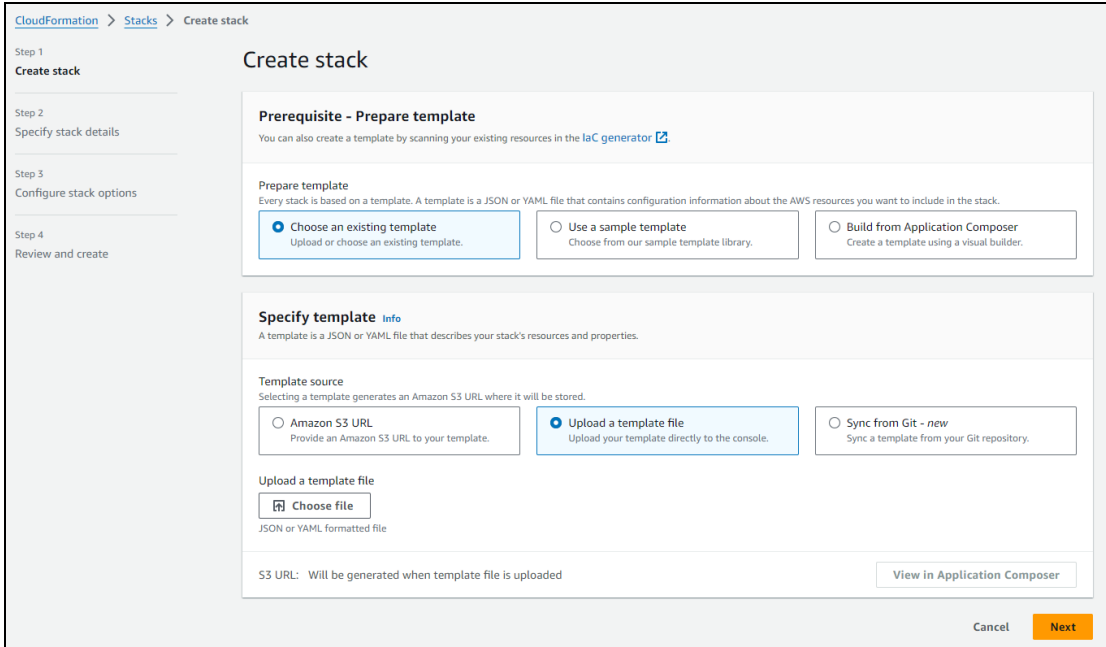

NOTE: vThunder instances should have the same versions; otherwise, traffic flow will be disrupted.

To create the Thunder virtual machines across different availability zones using A10-vThunder-3NIC-2VM template, perform the following steps:

1. Download **A10-vThunder_CFT-TEMPLATES > A10-vThunder-3NIC-2VM** template from [GitHub](#).
2. From AWS Management Console, navigate to **CloudFormation > Stacks > Create Stack > With new resources (standard)**.

The Create stack window is displayed.

Figure 19 : Create stack window

3. In the **Prerequisite - Prepare template** section, select **Choose an existing template**.

After selecting this option, the Specify template section is displayed.

4. In the **Specify template** section, select **Upload a template file** and click **Choose file** to browse and upload the following template file from the downloaded CFT folder:
CFT_TMPL_3NIC_2VM_ACROSS_AZ_HA.json

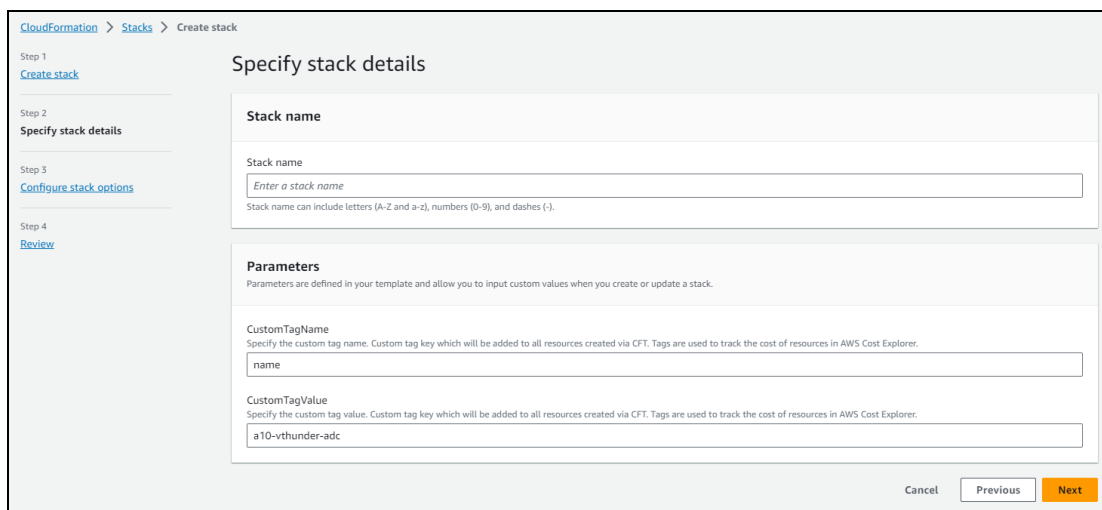

The selected template file name is displayed as the chosen file.

NOTE: This template contains pre-populated default values that can be modified as required. It does not create a new primary private IP address, virtual private IP address, security groups, subnets, and virtual private network.

5. Click **Next**.

The **Specify stack details** window is displayed.

Figure 20 : Specify stack details window

6. In the **Specify stack details** window, enter or select the following:

Table 5 : JSON Parameters

Resource Name	Description
Stack name	Specify a stack name containing letters (A-Z and a-z), numbers (0-9), and dashes (-). Here, the stack name is provided as <code>vth-3nic-2vm</code> .
AMIID	Specify the AMI ID of the required A10 vThunder image. By default, A10 Thunder ADC for Advanced Load Balancing - BYOL AMI ID is set for <code>us-east-</code>

Table 5 : JSON Parameters

Resource Name	Description
	<p>1 region.</p> <p>To get the AMI ID, go to the AWS Management Console > EC2 > Launch instance > Application and OS Images (Amazon Machine Image) > search for the relevant vThunder image and then copy the AMI ID.</p> <p>For more information on the available Thunder images with different capacities under respective regions, see List of ACOS AMI ID.</p>
AllocationIdEIPActiveThunder	<p>Specify an allocation ID of the required active elastic IP.</p> <p>This elastic IP address is the management public IP address of the Thunder instance 1.</p> <p>To get the allocation ID, go to the AWS Management Console > EC2 > Elastic IPs > <i><elastic_IP_address></i> > Summary and then copy the Allocation ID.</p>
AllocationIdEIPStandByThunder	<p>Specify an allocation ID of the required standby elastic IP.</p> <p>This elastic IP address is the management public IP address of the Thunder instance 2.</p> <p>To get the allocation ID, go to</p>

Table 5 : JSON Parameters

Resource Name	Description
	the AWS Management Console > EC2 > Elastic IPs > <elastic_IP_address> > Summary and then copy the Allocation ID .
AttachAlienIP	Select Yes if you want to use Alien IP. This will configure the HA setup with the Private IP (Alien IP). The default set value is No .
CreatePubVIP	Select Yes if VIP is a public IP address or select No if VIP is a private IP address.
CustomTagName	Specify the custom tag name. The custom tag key is added to all the resources created using the CFT template. This tag is used to track the cost of resources in the AWS Cost Explorer.
CustomTagValue	Specify the custom tag value. The custom tag key is added to all the resources created using the CFT template. This tag is used to track the cost of resources in the AWS Cost Explorer. The default custom tag value is a10-vthunder-adc .
DifferentAvailabilityZone	Select Yes if you want to deploy your vThunder instances across different availability zones. The default set value is No .

Table 5 : JSON Parameters

Resource Name	Description
DataInDestinationCidr	If you have selected Yes for AttachAlienIP, specify the CIDR for data-in interface that does not overlap with the selected VPC subnets.
DataOutDestinationCidr	If you have selected Yes for AttachAlienIP, specify the CIDR for data-out interface that does not overlap with the selected VPC subnets.
EC2Instance	<p>Select an instance/compute type supported for vThunder from the available list. By default, instance type is m4.xlarge which contains 4 vCPU and 16 GiB memory. The minimum requirement for vThunder is 4 vCPU and 16 GiB memory. For more information on product pricing, see AWS Marketplace.</p> <p>If the required instance type is not available in the list, go to AWS Management Console > EC2 > Launch instance > Find and copy the relevant instance type in the template. For more information, see Supported Instance Types.</p>
KeyPair	Select a keypair from the available list. A key pair is a set of security credentials which consist of a public key and a

Table 5 : JSON Parameters

Resource Name	Description
	private key. This keypair is used to verify your identity when connecting to an Amazon EC2 instance.
PrimaryPrivateIP	Specify the primary private IP address from data-in subnet CIDR. This IP address is the primary private IP address of the vThunder instance 1.
RouteTable	Specify the route table ID for the selected Virtual Private Network. This CFT template does not create a new route table.
SecondaryPrivateIPDataInActiveThunder	Specify data-in interface secondary IP for active vThunder instance. For example: <code>vth-inst-data-in-active-ip</code> . This CFT template does not create a new Virtual private IP address for virtual machine 1.
SecondaryPrivateIPDataInStandbyThunder	Specify data-in interface secondary IP for standby vThunder instance. For example: <code>vth-inst-data-in-standby-ip</code> . This CFT template does not create a new Virtual private IP address for virtual machine 2.
SecondaryPrivateIPDataOutActiveThunder	Specify data-out interface secondary IP for active

Table 5 : JSON Parameters

Resource Name	Description
	<p>vThunder instance. For example, <code>vth-inst-data-out-active-ip</code>.</p> <p>This CFT template does not create a new Virtual private IP address for virtual machine 1.</p>
SecondaryPrivateIPDataOutStandbyThunder	<p>Specify data-out interface secondary IP for standby vThunder. For example, <code>vth-inst-data-out-standby-ip</code>.</p> <p>This CFT template does not create a new Virtual private IP address for virtual machine 2.</p>
SecurityGroupData	<p>Select the required security group ID from the available list for data interface within the selected Virtual Private Network.</p>
SecurityGroupMgmt	<p>Select the required security group ID from the available list for the management interface within the selected Virtual Private Network.</p>
SubnetDataInActiveIDThunder	<p>Select the required subnet ID from the available list for the data traffic flow inward to active vThunder instance within the selected Virtual Private Network.</p> <p>This CFT template does not create a new subnet.</p>

Table 5 : JSON Parameters

Resource Name	Description
SubnetDataInStandByIDThunder	<p>Select the required subnet ID from the available list for the data traffic flow inward to standby vThunder instance within the selected Virtual Private Network.</p> <p>This CFT template does not create a new subnet.</p>
SubnetDataOutActiveIDThunder	<p>Select the required subnet ID from the available list for the data traffic flow outward from active vThunder instance within the selected Virtual Private Network.</p> <p>This CFT template does not create a new subnet.</p>
SubnetDataOutStandByIDThunder	<p>Select the required subnet ID from the available list for the data traffic flow outward from standby vThunder instance within the selected Virtual Private Network.</p> <p>This CFT template does not create a new subnet.</p>
SubnetMgmtActiveIDThunder	<p>Select the required subnet ID from the available list for managing active vThunder instance within the selected Virtual Private Network.</p> <p>This CFT template does not create a new subnet.</p>

Table 5 : JSON Parameters

Resource Name	Description
SubnetMgmtStandByIDThunder	<p>Select the required subnet ID from the available list for managing standby vThunder instance within the selected Virtual Private Network.</p> <p>This CFT template does not create a new subnet.</p>
Tenancy	<p>Select the required tenancy from the available list. Tenancy defines the distribution of EC2 instances across the physical hardware that affects pricing. It specifies if the Amazon EC2 instance is hosted on shared or single-tenant hardware.</p>
VPC	<p>Select the required Virtual Private Network ID to configure vThunder instance.</p>
ZoneActiveThunder	<p>Select a zone from the existing availability zones for active vThunder instance. AWS offers a range of options for managing availability and resiliency for your applications.</p> <p>Make use of the replicated VMs across the availability zones to protect your applications and data against the data center outages and maintenance events.</p>
ZoneStandByThunder	<p>Select a zone from the existing availability zones for standby</p>

Table 5 : JSON Parameters

Resource Name	Description
	<p>vThunder instance. AWS offers a range of options for managing availability and resiliency for your applications.</p> <p>Make use of the replicated VMs across the availability zones to protect your applications and data against the data center outages and maintenance events.</p>

7. Click **Next**.

The **Configure stack options** window is displayed.

8. Verify the other fields and change the values appropriately. (Optional)

9. Click **Next**.

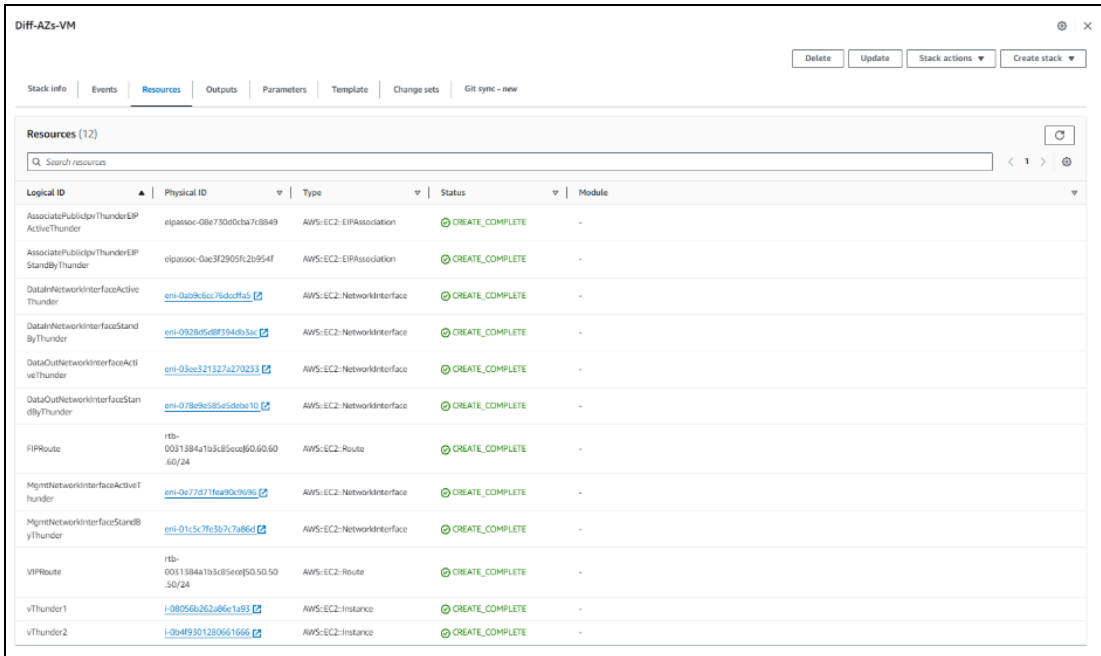

The **Review** *<stack_name>* window is displayed.

10. Verify if all the stack configurations are correct and then click **Submit**.

NOTE: The system may take a few minutes to create the resources and display the stack status as **CREATE_COMPLETE**.

11. Verify if the elastic IPs are created in the **AWS Management Console** > **CloudFormation** > **Stacks** > *<stack_name>* > **Resources** tab:

Figure 21 : Different AZs Resource Listing

12. [Access Thunder Virtual Machine.](#)
13. [Create Server Machine.](#)
14. [Create Client Machine.](#)

Configure Thunder

The following configurations can be applied to the deployed vThunder instance depending on your use case and requirement, see [Deployment Templates](#):

- [Change Password](#)
- [A10 License](#)
- [SSL Certificate](#)
- [Basic Server Load Balancer](#)
- [Backend Server Autoscaling](#)
- [High Availability Across Availability Zones](#)

Verify Deployment

To verify vThunder SLB deployment using CFT, perform the following steps:

1. Access the vThunder instances using CLI.
2. Run the following command on vThunder instance 1:

```
vThunder-Active(config)#show running-config
```

If the deployment is successful with basic SLB and HA Across AZs configuration, the following output is displayed:

```
!  
!

```

Figure 23 : vThunder instance 2 - Standby

4. Run the following command on vThunder instance 1:

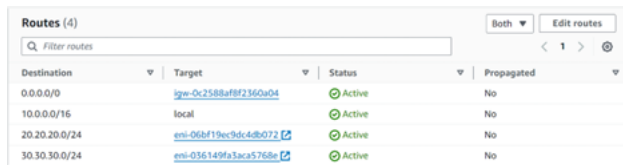

```

vThunder-Active (config) # vrrp-a force-self-standby enable
vThunder-Active (config) #
vThunder-ForcedStandby (config) #

```

Before the failover, note the interface ID in the route table.

Figure 24 : Routes - Before Failover

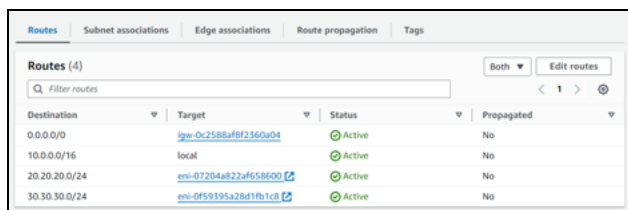

Destination	Target	Status	Propagated
0.0.0.0/0	igw-0c2588af8f2360u04	Active	No
10.0.0.0/16	local	Active	No
20.20.20.0/24	eni-066f19ec9dc448b072	Active	No
30.30.30.0/24	eni-036149fa3aca5768e	Active	No

At this point, IP switching occurs and the vThunder instance 2 prompt becomes:

```
vThunder-Active (config) #
```

After successful failover, the interface ID is changed in the route table.

Figure 25 : Routes - After Failover

Destination	Target	Status	Propagated
0.0.0.0/0	igw-0c2588af8f2360u04	Active	No
10.0.0.0/16	local	Active	No
20.20.20.0/24	eni-07204a822af658600	Active	No
30.30.30.0/24	eni-0f59395a28d11b1c8	Active	No

- If you want to make vThunder instance 1 active, run the following command on vThunder instance 1:

```
vThunder-ForcedStandby (config) #vrrp-a force-self-standby disable
```

At this point, IP switching occurs and the vThunder instance 1 prompt becomes:

```
vThunder-Active (config) #
```

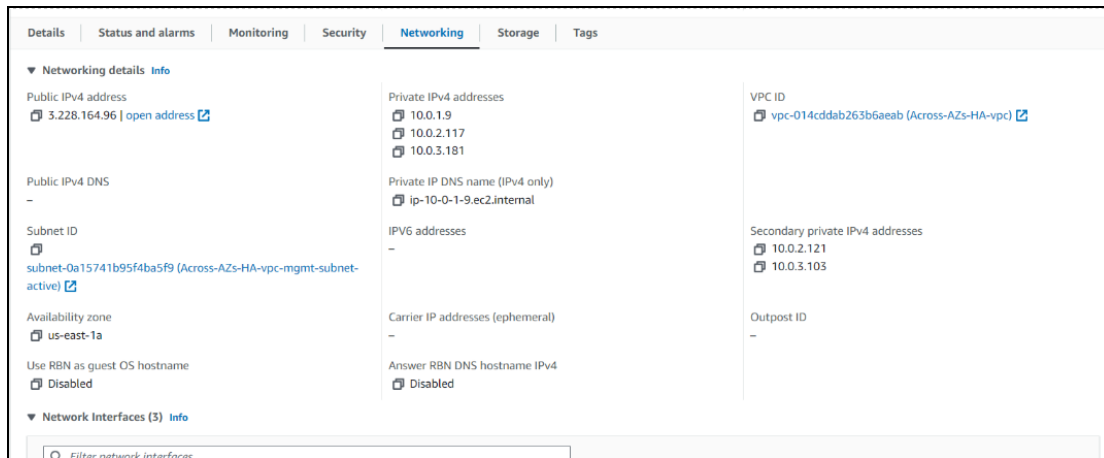

Verify Traffic Flow

To verify the traffic flow from client machine to server machine via vThunder, perform the following:

- From **AWS Management Console**, navigate to **EC2 > Instances**.
- Select the active vThunder instance name and then click the **Networking** tab.

- Note down the Data-In Subnet VIP address of the active vThunder instance.

Figure 26 : vThunder instance 1

- Select your client instance from the **Instances** list. Here, `vth-client` is the client instance name.
- Click **Connect**. A **Connect to instance** window with **EC2 Instance Connect** tab is displayed.
- Click **Connect**. A **Terminal** window is displayed.
- Replace the Data-In Subnet VIP address of the active vThunder instance noted above in the following command and then run the command in the Terminal window to send the traffic from the client machine:

```
curl <vThunder_instance_datain-nic_secondary_private_or_public_ip_vip>
```

Example for Private VIP

```
curl 10.0.2.121
```

Example for Public VIP

```
curl 3.214.248.169
```

Example for Alien IP

```
curl 20.20.20.20
```

- Verify if a response is received.
- SSH your client machine and run the following command to verify the HTTP

template traffic flow:

```
curl <vThunder_instance_datain-nic_secondary_private_or_public_ip_vip>:<port_number>/<host-match-string or url-match-string>/
```

Example for Private VIP

```
curl 10.0.2.121:80/s1/
```

Example for Public VIP

```
curl 3.214.248.169:80/s1/
```

Example for Alien IP

```
curl 20.20.20.20:80/s1/
```

Verify if a response is received from client server (For example: Apache Index page).

10. SSH your client machine and run the following commands to verify the Persist cookie template traffic flow:

- a. Verify the current cookie configuration:

```
curl --head <vThunder_instance_datain-nic_private_or_public_ip_vip>
```

- b. Run the following commands to save the cookies in the `cookie.txt` file:

```
curl -b cookie.txt -c cookie.txt <vThunder_instance_datain-nic_private_or_public_ip_vip>  
cat cookie.txt
```

Example for Private VIP

```
curl --head 10.0.2.121  
curl -b cookie.txt -c cookie.txt 10.0.2.121  
cat cookie.txt
```

Example for Public VIP

```
curl --head 3.214.248.169  
curl -b cookie.txt -c cookie.txt 3.214.248.169  
cat cookie.txt
```

Example for Alien VIP

```
curl --head 20.20.20.20
curl -b cookie.txt -c cookie.txt 20.20.20.20
cat cookie.txt
```

11. Run the following command on the active vThunder instance to view the persistence load-balancing statistics:

```
vThunder(config)#show slb persist
```

If the deployment is successful, the following summary persistence statistics is displayed:

	Total
-----	-----
URL hash persist (pri)	0
URL hash persist (sec)	0
URL hash persist fail	0
SRC IP persist ok	0
SRC IP persist fail	0
SRC IP hash persist(pri)	0
SRC IP hash persist(sec)	0
SRC IP hash persist fail	0
DST IP persist ok	0
DST IP persist fail	0
DST IP hash persist(pri)	0
DST IP hash persist(sec)	0
DST IP hash persist fail	0
SSL SID persist ok	0
SSL SID persist fail	0
Cookie persist ok	1
Cookie persist fail	0
Persist cookie not found	2
Persist cookie Pass-thru	0
Enforce higher priority	0

If the Persist-cookie configuration is successful, a value is displayed for the **Cookie persist ok** else the value is 0.

Thunder-3NIC-3VM

This template creates three new virtual machines with pre-loaded Thunder instance in the same region and zone and attaches three new network interface cards (NICs). These three vThunder instances are referred as Master Controller (Active), Site1 and Site2. Same template can be used to install identical number of resources in another region. The three vThunder instances in another region are referred as Member Controller, Site1 and Site2.

This template is used to setup disaster recovery site in a cross-region or hybrid cloud environment.

For more information, see [Create Thunder Virtual Machines](#).

NOTE: Use a suitable VM size that supports at least three NICs. For VM sizes, see [List of Supported Instance Types](#).

Figure 27 : Thunder ADC with GSLB

Additional Thunder configurations are available that can be applied as needed:

- [Change Password](#)
- [A10 License](#)
- [SSL Certificate](#)
- [Hybrid Cloud GSLB](#)

Various templates are available for different deployment needs.

For more information, see [Deployment Templates](#).

The following topics are covered:

Create Thunder Virtual Machines	87
Configure Thunder	98
Verify Deployment	99
Verify Traffic Flow	121

Create Thunder Virtual Machines

The A10-vThunder-3NIC-3VM template is used to create three Thunder virtual machines with three network interface cards each.

Before deploying this template, it is recommended to review the [Prerequisites](#).

To create Thunder virtual machines using the A10-vThunder-3NIC-3VM template, perform the following steps:

1. Download **A10-vThunder_CFT-TEMPLATES > A10-vThunder-3NIC-3VM** template from [GitHub](#).
2. From AWS Management Console, navigate to **CloudFormation > Stacks > Create Stack > With new resources (standard)**.

The Create stack window is displayed.

Figure 28 : Create stack window

3. In the **Prerequisite - Prepare template** section, select **Choose an existing template**.

After selecting this option, the Specify template section is displayed.

4. In the **Specify template** section, select **Upload a template file** and click **Choose file** to browse and upload the following template file from the downloaded CFT folder:

CFT_TMPL_3NIC_3VM.json

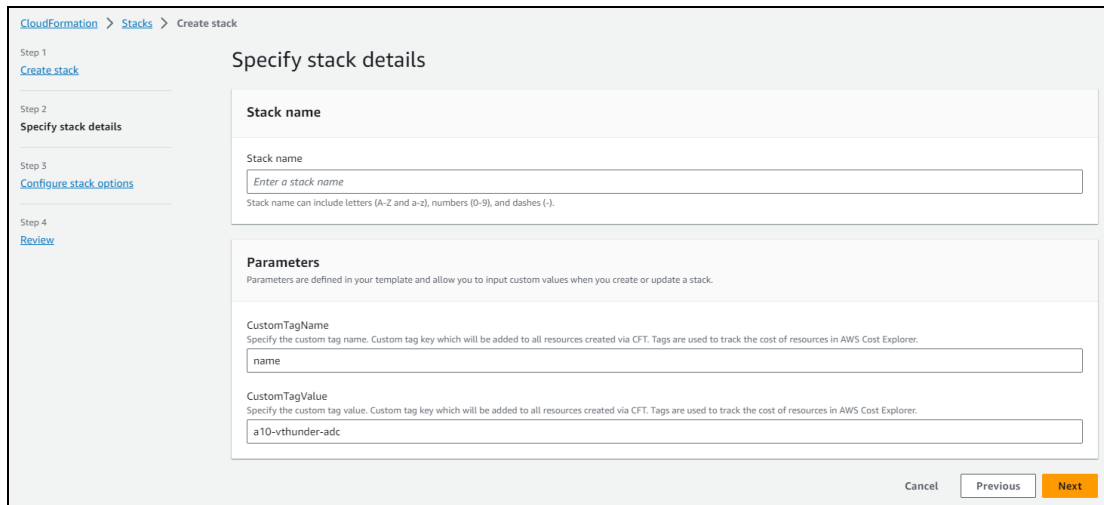

The selected template file name is displayed as the chosen file.

NOTE: This template contains pre-populated default values that can be modified as required. It does not create a new elastic public IP, primary private IP address, virtual private IP address, security groups, subnets, and virtual private network.

5. Click **Next**.

The **Specify stack details** window is displayed.

Figure 29 : Specify stack details window

6. In the **Specify stack details** window, enter or select the following:

Table 6 : JSON Parameters

Resource Name	Description
Stack name	<p>Specify a stack name containing letters (A-Z and a-z), numbers (0-9), and dashes (-).</p> <p>Here, the stack name is provided as <code>vth-rg1</code>.</p>
AMIID	<p>Specify the AMI ID of the required A10 vThunder image. By default, A10 Thunder ADC for Advanced Load Balancing - BYOL AMI ID is set for us-east-1 region.</p> <p>To get the AMI ID, go to the AWS Management Console > EC2 > Launch instance > Application and OS Images (Amazon</p>

Table 6 : JSON Parameters

Resource Name	Description
	<p>Machine Image) > search for the relevant vThunder image and then copy the AMI ID.</p> <p>For more information on the available Thunder images with different capacities under respective regions, see List of ACOS AMI ID.</p>
AllocationIdEIPThunderInstance11	<p>Specify an allocation ID of Thunder instance 1's elastic IP address.</p> <p>This elastic IP address is the management public IP address of the Thunder instance 1.</p> <p>To get the allocation ID, go to the AWS Management Console > EC2 > Elastic IPs > <i><elastic_IP_address></i> > Summary and then copy the Allocation ID.</p>
AllocationIdEIPThunderInstance12	<p>Specify an allocation ID of Thunder instance 1's elastic IP address.</p> <p>This elastic IP address is the virtual public IP address of the Thunder instance 1.</p>

Table 6 : JSON Parameters

Resource Name	Description
	<p>To get the allocation ID, go to the AWS Management Console > EC2 > Elastic IPs > <i><elastic_IP_address></i> > Summary and then copy the Allocation ID.</p>
AllocationIdEIPThunderInstance21	<p>Specify an allocation ID of Thunder instance 2's elastic IP address.</p> <p>This elastic IP address is the management public IP address of the Thunder instance 2.</p> <p>To get the allocation ID, go to the AWS Management Console > EC2 > Elastic IPs > <i><elastic_IP_address></i> > Summary and then copy the Allocation ID.</p>
AllocationIdEIPThunderInstance22	<p>Specify an allocation ID of Thunder instance 2's elastic IP address.</p> <p>This elastic IP address is the virtual public IP (VIP) address of the Thunder instance 2.</p> <p>To get the allocation ID, go to the AWS Management Console > EC2 > Elastic IPs ></p>

Table 6 : JSON Parameters

Resource Name	Description
	<p><i><elastic_IP_address></i> > Summary and then copy the Allocation ID.</p>
AllocationIdEIPThunderInstance31	<p>Specify an allocation ID of Thunder instance 3's elastic IP address.</p> <p>This elastic IP address is the management public IP address of the Thunder instance 3.</p> <p>To get the allocation ID, go to the AWS Management Console > EC2 > Elastic IPs > <i><elastic_IP_address></i> > Summary and then copy the Allocation ID.</p>
AllocationIdEIPThunderInstance32	<p>Specify an allocation ID of Thunder instance 3's elastic IP address.</p> <p>This elastic IP address is the virtual public IP (VIP) address of the Thunder instance 3.</p> <p>To get the allocation ID, go to the AWS Management Console > EC2 > Elastic IPs > <i><elastic_IP_address></i> > Summary and then copy the Allocation ID.</p>

Table 6 : JSON Parameters

Resource Name	Description
CustomTagName	Specify the custom tag name. The custom tag key is added to all the resources created using the CFT template. This tag is used to track the cost of resources in the AWS Cost Explorer.
CustomTagValue	Specify the custom tag value. The custom tag key is added to all the resources created using the CFT template. This tag is used to track the cost of resources in the AWS Cost Explorer. The default custom tag value is a10-vthunder-adc .
EC2Instance	Select an instance/compute type supported for vThunder from the available list. By default, instance type is m4.xlarge which contains 4 vCPU and 16 GiB memory. The minimum requirement for vThunder is 4 vCPU and 16 GiB memory. For more information on product pricing, see AWS Marketplace .

Table 6 : JSON Parameters

Resource Name	Description
	If the required instance type is not available in the list, go to AWS Management Console > EC2 > Launch instance > Find and copy the relevant instance type in the template. For more information, see Supported Instance Types .
IPThunder1	Specify the primary private IP of Thunder instance 1's data-in subnet.
IPThunder2	Specify the primary private IP of Thunder instance 2's data-in subnet.
IPThunder3	Specify the primary private IP of Thunder instance 3's data-in subnet.
KeyPair	Select a keypair from the available list. A key pair is a set of security credentials which consist of a public key and a private key. This keypair is used to verify your identity when connecting to an Amazon EC2 instance.
SecurityGroupData	Select the required

Table 6 : JSON Parameters

Resource Name	Description
	security group ID from the available list for data interface within the selected Virtual Private Network.
SecurityGroupMgmt	Select the required security group ID from the available list for the management interface within the selected Virtual Private Network.
SubnetDataInID	Select the required subnet ID from the available list for the data traffic flow inward to vThunder within the selected Virtual Private Network.
SubnetDataOutID	Select the required subnet ID from the available list for the data traffic flow outward from vThunder within the selected Virtual Private Network.
SubnetMgmtID	Select the required subnet ID from the available list for managing vThunder within the selected Virtual Private Network.
Tenancy	Select the required tenancy from the available list. Tenancy defines the distribution of EC2 instances across the

Table 6 : JSON Parameters

Resource Name	Description
	physical hardware that affects pricing. It specifies if the Amazon EC2 instance is hosted on shared or single-tenant hardware.
VIPThunder1	Specify the virtual private IP of Thunder instance 1's data-in subnet.
VIPThunder2	Specify the virtual private IP of Thunder instance 2's data-in subnet.
VIPThunder3	Specify the virtual private IP of Thunder instance 3's data-in subnet.
VPCID	Select the required Virtual Private Network ID to configure vThunder.
Zone	Select a zone from the existing availability zones. AWS offers a range of options for managing availability and resiliency for your applications.

Table 6 : JSON Parameters

Resource Name	Description
	<p>NOTE: Make use of the replicated VMs across the availability zones to protect your applications and data against the data center outages and maintenance events.</p>

7. Click **Next**.

The **Configure stack options** window is displayed.

8. Verify the other fields and change the values appropriately. (Optional)

9. Click **Next**.

The **Review** *<stack_name>* window is displayed.

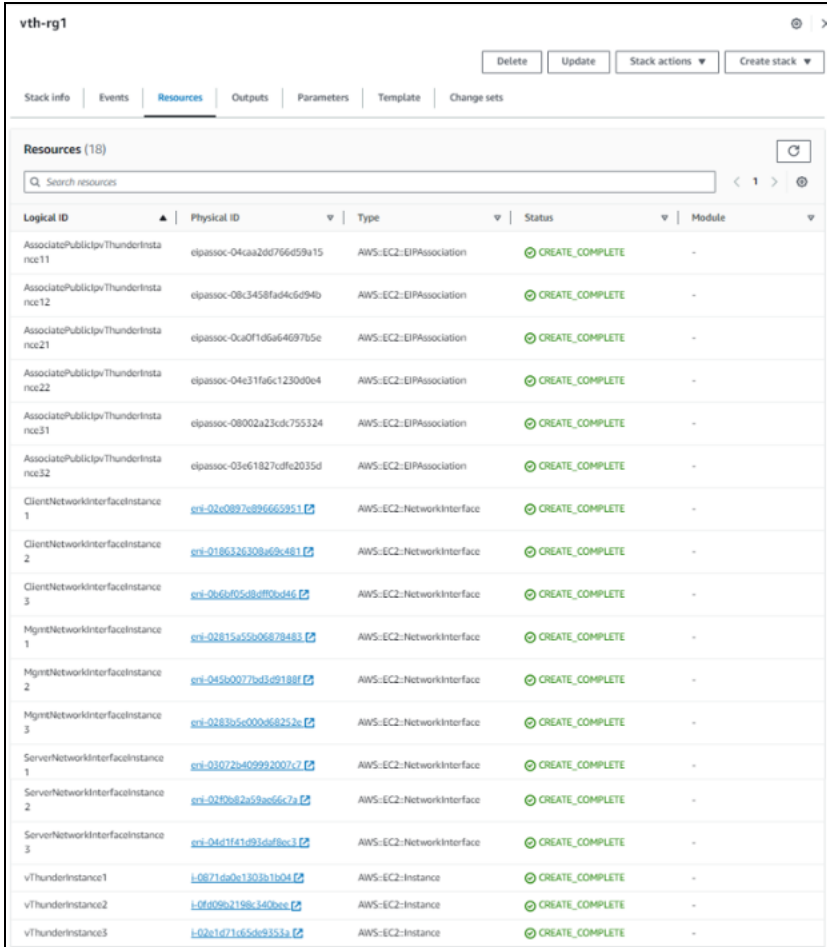

10. Verify if all the stack configurations are correct and then click **Submit**.

NOTE: The system may take a few minutes to create the resources and display the stack status as **CREATE_COMPLETE**.

11. Verify if all the listed resources are created in the **AWS Management Console** > **CloudFormation** > **Stacks** > *<stack_name>* > **Resources** tab:

- Three vThunder instances
- One management and two data interface for each vThunder instance

Figure 30 : Resource listing

12. [Access Thunder Virtual Machine.](#)
13. [Create Server Machine.](#)
14. [Create Client Machine.](#)

Configure Thunder

The following configurations can be applied to the deployed vThunder instance depending on your use case and requirement, see [Deployment Templates](#):

- [Change Password](#)
- [A10 License](#)

- [SSL Certificate](#)
- [Hybrid Cloud GSLB](#)

Verify Deployment

To verify deployment using CFT, perform the following steps:

1. Access the vThunder instances using CLI.
2. Verify SLB configuration on the following vThunder instances:

CONTROLLER - Master configuration

Run the following command:

```
vThunder-gslb:Master (config) (NOLICENSE) # show running-config
```

If the deployment is successful, the following controller and site configuration is displayed on vThunder master controller:

```

3. Verify GSLB group information on the following vThunder instances:

CONTROLLER - Master configuration

- a. Run the following command:

```
vThunder-gslb:Master(NOLICENSE) #show gslb group
```

- b. Verify if the public ip of member controller is displayed in the response:

```

Pri = Priority, Attrs = Attributes
S-Cfg = Secure Config
S-State = Secure Status
  D = Disabled, L = Learn
  P = Passive, * = Master
  E = Enabled, EF = Enable-Fallback
  Unsec = Unsecure, Unkwn = Unknown
  Estng = Establishing, Estd = Established
Group: default, Master: local
Member          Sys-ID   Pri Attrs  Status  S-
Cfg S-State Address
-----
-----
local           7b8a5001 255 L*      OK
vThunder       58dd5c28 100 PL     Synced  D
  Unsec   13.58.227.170
```

CONTROLLER - Member configuration

- a. Run the following command:

```
vThunder-gslb:Member(NOLICENSE) #show gslb group
```

Verify if the public ip of master controller is displayed in the response:

```

Pri = Priority, Attrs = Attributes
S-Cfg = Secure Config
S-State = Secure Status
    D = Disabled, L = Learn
    P = Passive, * = Master
    E = Enabled, EF = Enable-Fallback
    Unsec = Unsecure, Unkwn = Unknown
    Estng = Establishing, Estd = Established
Group: default, Master: vThunder
Member          Sys-ID   Pri Attrs  Status  S-
Cfg S-State Address
-----
-----
local           58dd5c28 100 L      OK
vThunder       7b8a5001 255 L*    Synced  D
    Unsec    18.209.143.246

```

4. Verify the GSLB protocol information on the following vThunder instances:

CONTROLLER - Master configuration

Run the following command:

```
vThunder-gslb:Master (NOLICENSE) #show gslb protocol
```

The following configuration is displayed on vThunder master controller:

```

GSLB site: eastus_1
  SLB device: slb1 (10.1.1.170:10578) Established

GSLB protocol is disabled for site devices.

```

NOTE: If you want to access the vThunder instances using GUI, re-login the instances using the new admin user password and NOT the *EC2 Instance ID*.

Verify Traffic Flow

The traffic flow can be tested using the following:

- [DNS Lookup](#)
- [WGET](#)

DNS Lookup

To verify the traffic flow from via vThunder, perform the following:

1. Perform a DNS lookup on server1 of region1 using the master controller's client-side data interface public IP in the following command:

```
$ dig @master_controller_data_public_IP www.gslb.a10.com
```

The master controller's client-side data interface public IP is used as DNS server IP. You can get this data interface public IP from **AWS Management Console** > **EC2** > **Instances** > <stack_name_master_controller_region1> > **Networking** > **Elastic IP address**.

Figure 31 : Master Controller Data Interface Public IP

Name	Allocated IPv4 address	Type	Address pool	Allocation ID
vth-stack1-inst1-data-nic1-ip	54.202.82.33	Public IP	amazon	eipalloc-0d0da9cd0ed5a80c9
vth-stack1-inst1-mgmt-nic1-ip	54.172.152.132	Public IP	amazon	eipalloc-0ce743fee2c34212f

The following response is received:

```
$ dig @34.202.82.33 www.gslb.a10.com
; <<>> DiG 9.18.1-Ubuntu <<>> @34.202.82.33 www.gslb.a10.com

```

The response is received with site devices secondary data1 public IPs based on round robin.

WGET

To verify the traffic flow via vThunder, perform the following:

1. From **AWS Management Console**, navigate to **EC2 > Instances**.
2. Select any one of the server instances assigned to the site devices.

Here, `vth-stack1-server1` is the server instance name.

3. Click **Connect**.

A **Connect to instance** window with **EC2 Instance Connect** tab is displayed.

4. Click **Connect**.

A **Terminal** window is displayed.

5. Run the following command in the Terminal window to create an Apache Server virtual machine:

```
$ sudo apt install apache2
```

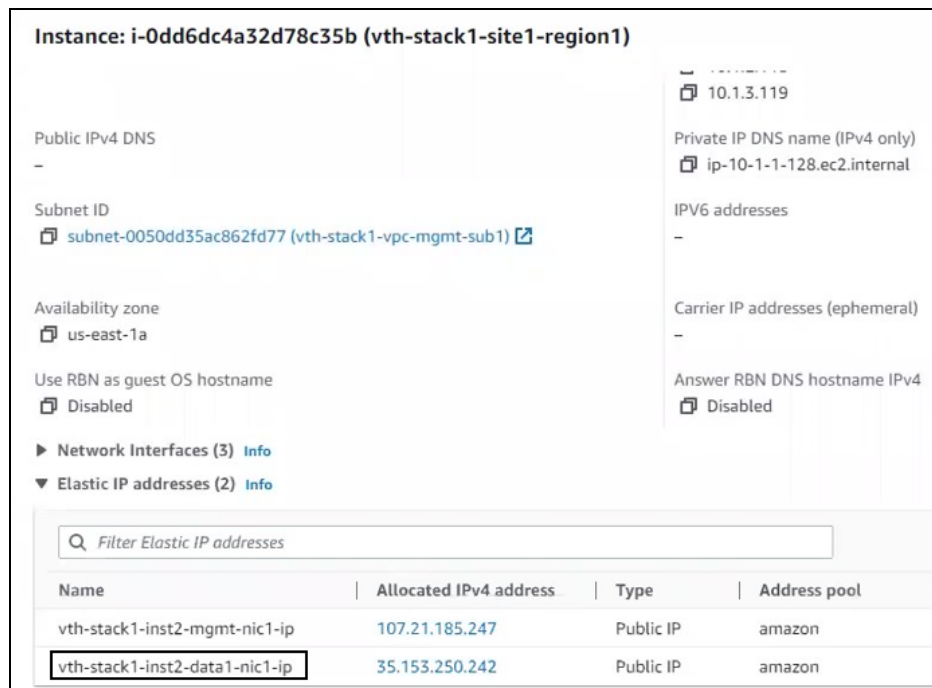

While the Apache server is getting installed, you get a prompt to continue further. Enter 'Y' to continue. After the installation is complete, a newline prompt is displayed.

6. From **AWS Management Console > EC2 > Instances**, select the site instance of the corresponding server on which Apache was installed.

Here, `vth-stack1-site1-region1` is the site instance.

7. Navigate to **Networking** tab > **Elastic IP addresses** and copy the **Allocated IPv4 address** of site instance data interface.

Figure 33 : Site Instance Data Interface Public IP

Instance: i-0dd6dc4a32d78c35b (vth-stack1-site1-region1)

Public IPv4 DNS: -

Subnet ID: subnet-0050dd35ac862fd77 (vth-stack1-vpc-mgmt-sub1)

Availability zone: us-east-1a

Use RBN as guest OS hostname: Disabled

Network Interfaces (3) Info

Elastic IP addresses (2) Info

Name	Allocated IPv4 address	Type	Address pool
vth-stack1-inst2-mgmt-nic1-ip	107.21.185.247	Public IP	amazon
vth-stack1-inst2-data1-nic1-ip	35.153.250.242	Public IP	amazon

8. Run the following command on the server1 of region1:

```
$ wget site_device_data-public-IP
```

The following response is received:

```
$ wget 35.153.250.242
--2023-01-09 17:49:47-- http://35.153.250.242/
Connecting to 35.153.250.242:80... connected.

ADC Configuration Templates

This section guides you in applying new Application Delivery Controller (ADC) configurations on Thunder using Python scripts.

[Table 7](#) provides an overview of the different supported Thunder configurations. These configurations are optional. You can choose to apply them based on your specific use cases. For more information, see [Deployment Templates](#).

Table 7 : Supported Thunder configurations

Configuration	Description
Change Password	Applies a new vThunder instance password. NOTE: After the deployment of vThunder instance, it is highly recommended to change the default password for <code>admin</code> user.
Basic Server Load Balancer	Applies an SLB configuration for inbound traffic, outbound traffic, policies, server grouping, and routing to destination virtual servers.
Backend Server Autoscaling	Applies an SLB configuration automatically whenever backend app/web servers are autoscaled. When the backend web/app servers are in an autoscale group within the AWS cloud,

Table 7 : Supported Thunder configurations

Configuration	Description
	autoscale-in or autoscale-out of the server triggers a Lambda function for applying or removing SLB server configuration in Thunder.
A10 License	<p>Applies an A10 license to the vThunder instance.</p> <p>NOTE: A10 Thunder is a proprietary software that requires either a trial or BYOL (Bring Your Own License) subscription. However, pre-licensed subscription-based images from the AWS Marketplace do not require this configuration.</p>
SSL Certificate	Applies a server connection certificate configurations. A Secure Sockets Layer (SSL) certificate is a digital certificate that verifies a website's identity and facilitates an encrypted connection. SSL is a security protocol that establishes an encrypted link between a web server

Table 7 : Supported Thunder configurations

Configuration	Description
	and a web browser.
High Availability	<p>Applies high availability configuration. This configuration automatically synchronizes Thunder configuration between the active and standby Thunder instances. In the event of a failover, the other standby Thunder instance is designated as active to ensure uninterrupted traffic routing. For this functionality, it is essential for both Thunder instances to have identical resources and configurations.</p>
High Availability Across Availability Zones	<p>Applies high availability configuration. In this configuration, both vThunder instances are either in same availability zone having six subnets for each interface or across different availability zones have 3 subnets each in same region. This configuration automatically synchronizes vThunder configuration between the active and standby vThunder instances. In the event of a failover, the other standby</p>

Table 7 : Supported Thunder configurations

Configuration	Description
	vThunder instance is designated as active to ensure uninterrupted traffic routing. For this functionality, it is essential for both vThunder instances to present in same VPC.
Autoscale Server	Creates Autoscaling Group (ASG) and Lambda Function. It configures S3 Bucket to store the template resources.
Hybrid Cloud GSLB	<p>Applies a disaster recovery configuration using a global server load balancer across any two regions or locations, whether within the same cloud, hybrid-cloud or on-premise. It requires a minimum of two Thunder instances in each region or location —one acting as the master controller and the other as a site device.</p> <p>Multiple site devices can be configured but it is recommended to have a minimum of three site devices for seamless failover and effective disaster recovery.</p> <p>For a configuration with</p>

Table 7 : Supported Thunder configurations

Configuration	Description
	<p>three Thunders instances, the recommended setup includes one as the master controller and the other two as site devices.</p> <p>Ensure that both regions have identical set of resources.</p> <p>To create and install three thunder instances in one region use Thunder-3NIC-3VM template. The same template can be used to install Thunder instances in another region.</p>

Change Password

After provisioning the vThunder instance, you can change the vThunder instance password at any given time.

NOTE: It is highly recommended to change the default password. For default password, see [Support Information](#).

To change the password of the deployed vThunder instance, perform the following steps:

1. Download **A10-vThunder_ADC-CONFIGURATION > CHANGE-PASSWORD** template from [GitHub](#).
2. From the Start menu, open command prompt and navigate to the downloaded template.

- Open the CHANGE_PASSWORD_PARAM with a text editor.

NOTE: Each parameter has a default value mentioned in the parameter file, which can be modified as required.

- Configure the following parameters:

Table 8 : JSON Parameters

Resource Name	Description
Public IP List	Specify the Public IP address of one or more vThunder instance/s of vThunders to change password. <pre>"publicIpList": ["X.X.X.X", "X.X.X.X"],</pre>
Secret manager name	Specify the Secret manager name for Autoscaling to add servers only. <pre>"secretManagerName": "secret-manager-name"</pre>

- From the Start menu, open the command prompt and navigate to the downloaded template to run the following command:

```
C:\Users\TestUser\A10-vThunder_ADC-CONFIGURATION\CHANGE-PASSWORD>
python ./CHANGE_PASSWORD.py
```

A message prompt displaying the primary conditions for password validation appears:

```
Primary conditions for password validation, user should provide the new
password according to the given combination:
```

```
Minimum length of 9 characters
```

```
Minimum lowercase character should be 1
```

```
Minimum uppercase character should be 1
```

```
Minimum number should be 1
```

```
Minimum special character should be 1
```

```
Should not include repeated characters
```

```
Should not include more than 3 keyboard consecutive characters.
```

- Provide the vThunder instance's default password as the EC2 instance ID, new

password, and then confirm the new password when prompted:

```
Enter vThunder [x.x.x.x] password: ***
Enter vThunder new password: ****
Confirm new password: ****
```

NOTE: The default password is provided by the A10 Networks Support. The new password should meet the default password policy criteria. For more information, see [Default Password Policy](#).

7. If the password is successfully updated in Secret Manager, the following message is displayed:

```
vThunder [x.x.x.x] Password changed successfully.
Configurations are saved on partition: shared
```

8. Enter 'yes' to update the password in the Secret Manager.

```
Do you want to update password in Secret Manager? [yes/no]yes
```

9. If the password is changed successfully, the following message is displayed:

```
Successfully updated password in Secret Manager.
```

Basic Server Load Balancer

This template configures the vThunder instance as a Server Load Balancer (SLB) to evenly distribute the traffic across a set of predefined servers and requires manual scaling.

To configure vThunder as an SLB, perform the following steps:

1. Download **A10-vThunder_ADC-CONFIGURATION > BASIC-SLB** template from [GitHub](#).
2. From the Start menu, open the command prompt and navigate to this downloaded template.
3. Open the SLB_CONFIG_PARAM.json with a text editor.

NOTE: Each parameter has a default value mentioned in the parameter file, which can be modified as required.

4. Configure the following parameters:

Table 9 : JSON Parameters

Resource Name	Description
Template HTTP	<p>Specify the value as 1 if you want to configure the HTTP template. For more information on SLB HTTP template, see <i>Command Line Interface Reference</i>.</p> <pre>"template_http": 0,</pre> <p>NOTE: By default, the template HTTP value is 0.</p>
Template Persist Cookie	<p>Specify the value as 1 if you want to configure the Persist-Cookie template. For more information on SLB persist cookie template, see <i>Command Line Interface Reference</i>.</p> <pre>"template_persist_cookie": 0,</pre> <p>NOTE: By default, the template Persist-Cookie value is 0.</p>
vThunder instance username	<p>Specify a 'Read/Write/HM' privilege username.</p> <pre>"vth_username": "admin",</pre> <p>NOTE: The vThunder instance user should have 'Read/Write/HM' privilege to configure vThunder as an SLB.</p>
Data Interface Count	<p>Specify the number of data NICs. The value should be '1' for 2 NICs and '2' for 3 NICs.</p> <pre>"data_interface_count":1,</pre>
Public IP addresses	<p>Specify the Public IP address of one or more vThunder instance/s depending on the deployed template.</p> <pre>"publicIpList": ["X.X.X.X", "X.X.X.X"],</pre>
SLB	Specify name and private IP address of one or more SLB servers.

Table 9 : JSON Parameters

Resource Name	Description
server details	<pre data-bbox="560 373 1079 856"> "server_details": { "value": [{ "server-name": "server1", "pvt-ip-address": "X.X.X.X" }, { "server-name": "server2", "pvt-ip-address": "X.X.X.X" }] }, </pre>
SLB server ports	<p data-bbox="477 877 982 911">Specify the SLB Server ports details.</p> <pre data-bbox="560 949 1015 1600"> "slbServerPortList": { "value": [{ "port-number": 53, "protocol": "udp" }, { "port-number": 80, "protocol": "tcp" }, { "port-number": 443, "protocol": "tcp" }] }, </pre>
Persist Cookie Template	<p data-bbox="477 1625 1122 1696">Specify the Persist Cookies template details if <code>templatePersistCookie = 1</code>.</p>

Table 9 : JSON Parameters

Resource Name	Description
	<pre>"cookie-list":{ "value": [{ "name": "persist-cookie", "expire": 60, "encrypt-level": 0, "cookie-name":"a10-cookies", "match-type": 1, "service-group":1 }] },</pre>
HTTP Template	Specify the HTTP template details if <code>templateHTTP = 1</code> .

Table 9 : JSON Parameters

Resource Name	Description
	<pre> "httpClient": { "value": [{ "name": "host-switch", "host-switching": [{ "host-switching-type": "contains", "host-match-string": "s1", "host-service-group": "sg80" }] }, { "name": "url-switch", "url-switching": [{ "url-switching-type": "regex-match", "url-match-string": "s1", "url-service-group": "sg80" }] }] }, </pre>
Virtual Server	<p>Specify virtual server details.</p> <p>The virtual server default name is “vip”. This is the private primary (for 2NIC-1VM) and secondary (for 3NIC-2VM) IP address of Ethernet1.</p> <hr/> <p>NOTE: To get the vip address after deploying the vThunder instances, EC2 > Instances > <stack_name_inst1> > Networking.</p> <hr/>

Table 9 : JSON Parameters

Resource Name	Description
	<p>If you want to configure an HTTP template (<code>templateHTTP = 1</code>), provide the HTTP template name in the <code>template-http</code> parameter.</p> <p>If you want to configure a Persist-Cookie template (<code>templatePersistCookie = 1</code>), provide the Persist-Cookie template name in the <code>template-persist-cookie</code> parameter.</p>

Table 9 : JSON Parameters

Resource Name	Description
	<pre> "virtual_Server_List": { "virtual-server-name": "vip", "eth1-ip-address": "X.X.X.X", "metadata": { "description": "Specify ethernet 1 primary private IP address in case of SLB without High Availability and secondary private IP address in case of SLB with High Availability." }, "value": [{ "port-number": 53, "protocol": "udp", "auto": 1, "service-group": "sg53" }, { "port-number": 80, "protocol": "http", "auto": 1, "service-group": "sg80", "template-http": "url-switch", "template-persist-cookie": "persist-cookie" }, { "port-number": 443, "protocol": "https", "auto": 1, "service-group": "sg443", "template-http": "url-switch", "template-persist-cookie": "persist-cookie" }] }, </pre>

Table 9 : JSON Parameters

Resource Name	Description
	<p>NOTE: Either <code>host-switching-template-name</code> Or <code>url-switching-template-name</code> can be used in the <code>template-http</code>.</p>
Service Group List	<p>Specify the SLB Service group.</p> <pre data-bbox="480 533 1417 1241"> "serviceGroupList": { "value": [{ "name": "sg443", "protocol": "tcp" }, { "name": "sg53", "protocol": "udp" }, { "name": "sg80", "protocol": "tcp" }] } </pre> <p>NOTE: if you want to configure service groups for each server, the number of members should be equal to the total number of servers. For example, if two servers are added in the parameter file then the members in the member list should also be two, one for server1 and the other for server2.</p>

5. Verify if all the configurations in the SLB_CONFIG_PARAM.json file are correct and save the changes.
6. Run the following command to configure the vThunder instance/s as an SLB:

```

C:\Users\TestUser\A10-vThunder_ADC-CONFIGURATION\BASIC-SLB> python
./SLB_CONFIG.py

```

7. Provide password for the vThunder instances/s whose IP address is mentioned in the SLB_CONFIG_PARAM.json file.

If SLB is configured successfully for 2NIC-1VM, the following message is displayed:

```
Enter vThunder [x.x.x.x] Password: *****
Successfully configuring ethernet ip 1
Do you want to configure SLB Server? [yes/no]yes
Successfully configured server server1
Successfully configured service group.
Successfully configured http template.
Successfully configured slb persist cookie.
Successfully configured virtual servers.
Configurations are saved on partition: shared
Successfully logged out from vThunder.
-----
```

The above configuration has one server, an HTTP template, and a Persist-Cookie template configured for 2NIC-1VM.

If SLB is configured successfully for 3NIC-2VM, the following message is displayed:

```
Enter vThunder [x.x.x.x] Password: *****
Successfully configuring ethernet ip 1
Successfully configuring ethernet ip 2
Do you want to configure SLB Server? [yes/no]yes
Successfully configured server server1
Successfully configured server server2
Successfully configured service group.
Successfully configured http template.
Successfully configured slb persist cookie.
Successfully configured virtual servers.
Configurations are saved on partition: shared
Successfully logged out from vThunder.
-----
Enter vThunder [x.x.x.x] Password: *****
Successfully configuring ethernet ip 1
Successfully configuring ethernet ip 2
Do you want to configure SLB Server? [yes/no]yes
Successfully configured server server1
Successfully configured server server2
Successfully configured service group.
Successfully configured http template.
Successfully configured slb persist cookie.
Successfully configured virtual servers.
Configurations are saved on partition: shared
Successfully logged out from vThunder.
-----
```

The above configuration has two servers, an HTTP template, and a Persist-Cookie template configured for 3NIC-2VM.

8. In case of only basic SLB configuration without High availability, run the following commands on both the Thunder instances:

```
vth-inst1#config
vth-inst1(config)# ip route 0.0.0.0 /0 10.0.2.1
vth-inst1(config)# write memory
Building configuration...
Write configuration to default primary startup-config
[OK]
vth-inst1(config)#
```

Backend Server Autoscaling

This template configures vThunder instance as a Server Load Balancer (SLB) to automate the scaling process allowing dynamic adjustment of servers based on the workload.

NOTE: Configure vThunder with basic SLB before configuring SLB on Backend Autoscale.

To configure a Backend Autoscale Server, perform the following steps:

1. [Create S3 Bucket](#)
2. [Create AWS Secrets Manager secret](#)
3. [Create vThunder credentials secret](#)
4. [Create Lambda Function and Autoscaling Group](#)
5. [Configure Lambda Function and ASG](#)

Create S3 Bucket

Amazon Web Services' (AWS) Simple Storage Service (S3) bucket is used to store the template resources. Therefore, you need to create the S3 bucket or you can use an existing one and then upload the SLB configuration file on AWS using this S3 bucket.

To create an S3 bucket, perform the following steps:

1. Download **A10-vThunder_ADC-CONFIGURATION > CONFIG-SLB_ON_BACKEND-AUTOSCALE** template from [GitHub](#).
2. Run the following command to create an S3 bucket and store the Lambda function python script:

```
PS C:\Users\TestUser\A10-vThunder_ADC-CONFIGURATION\CONFIG-SLB_ON_BACKEND-AUTOSCALE> python ./AUTOSCALE_SERVER_S3_UPLOAD_1.py
```

3. Enter a unique bucket name and the region where you want to create the new bucket.

NOTE: The region for S3 bucket and ASG should be the same.

```
Enter bucket name: <bucket_name>
Enter region: <region>
```

If S3 bucket is created successfully, a message 'File uploaded in S3 bucket successfully' is displayed.

4. Verify if the S3 bucket is created in the **AWS Management Console > Buckets > <bucket_name>**.

Figure 34 : S3 Bucket

The AUTOSCALE_SERVER_PACKAGE.zip is uploaded.

If you are using an existing S3 bucket, the zip file should be uploaded in this bucket.

NOTE: To delete the S3 bucket, see [Delete the resources](#).

Create AWS Secrets Manager secret

To create AWS Secrets Manager secret, if not created already, go to **AWS Management Console > Secrets Manager > Store a new secret** and add the following:

Table 10 : AWS Key value pair

Key	Value
Secret Type	Other type of secret
Key/value pairs	Provide the following values: <ul style="list-style-type: none"> • aws_access_key_id - <i><your aws access key id></i> • aws_secret_access_key - <i><your aws secret access key></i>
Encryption key	aws/secretsmanager
Secret name	<i><your AWS keys secret manager name></i>

For more information, see

https://docs.aws.amazon.com/secretsmanager/latest/userguide/create_secret.html

Create vThunder credentials secret

To create vThunder credentials secret, if not created already, go to **AWS Management Console > Secrets Manager > Store a new secret** and add the following:

Table 11 : vThunder Key value pair

Key	Value
Secret Type	Other type of secret
Key/value pairs	Provide the following values: <ul style="list-style-type: none"> • username - <i><vThunder username></i> • password - <i><vThunder password></i>
Encryption key	aws/secretsmanager

Table 11 : vThunder Key value pair

Key	Value
Secret name	<your secret manager name>

For more information, see

https://docs.aws.amazon.com/secretsmanager/latest/userguide/create_secret.html

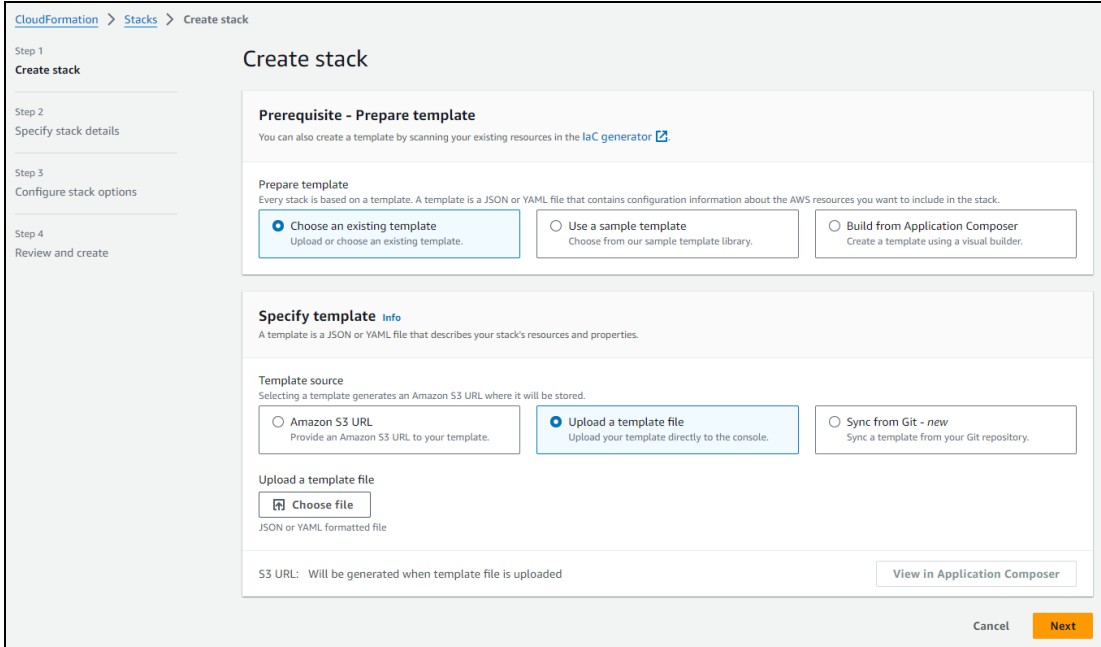

Create Lambda Function and Autoscaling Group

To create Lambda Function and Autoscaling Group, perform the following steps:

1. From AWS Management Console, navigate to **CloudFormation > Stacks > Create Stack > With new resources (standard)**.

The Create stack window is displayed.

Figure 35 : Create stack window

2. In the **Prerequisite - Prepare template** section, select **Choose an existing template**.

After selecting this option, the **Specify template** section is displayed.

- In the **Specify template** section, select **Upload a template file** and click **Choose file** to browse and upload the following template file from the downloaded CFT template:

AUTOSCALE_SERVER_PARAM.json

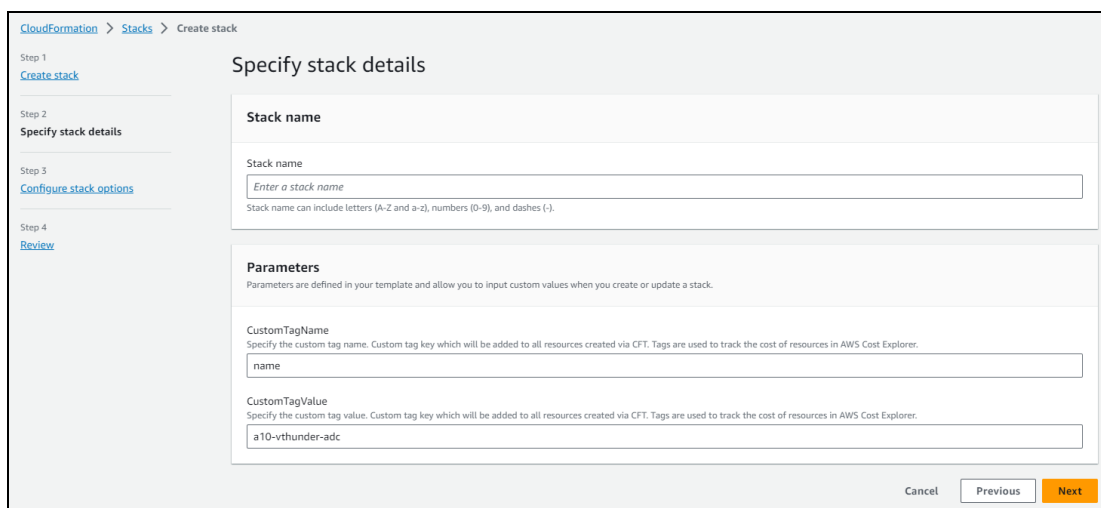

The selected template file name is displayed as the chosen file.

NOTE: This template contains pre-populated default values that can be modified as required and do not create a new subnet.

- Click **Next**.

The **Specify stack details** window is displayed.

Figure 36 : Specify stack details window

- In the **Specify stack details** window, enter or select the following:

Table 12 : JSON Parameters

Resource Name	Description
Stack name	Specify a stack name containing letters (A-Z and a-z), numbers (0-9), and dashes (-). Here, the stack name is provided as <code>asg</code> .
AMIID	Specify the AMI ID of the required A10 vThunder image. By default, A10 Thunder ADC for Advanced Load Balancing - BYOL

Table 12 : JSON Parameters

Resource Name	Description
	<p>AMI ID is set for us-east-1 region.</p> <p>To get the AMI ID, go to the AWS Management Console > EC2 > Launch instance > Application and OS Images (Amazon Machine Image) > search for the relevant vThunder image and then copy the AMI ID.</p> <p>For more information on the available Thunder images with different capacities under respective regions, see List of ACOS AMI ID.</p>
AWSecretManager	Specify the existing secret manager name containing AWS access and secret access keys. AWS Secret Manager helps you to securely encrypt, store and retrieve credentials for your databases and other services.
CPUPolicyTargetValue	Specify the value to auto scale based on a target value of CPU utilization. For more information, see here .
KeyPair	Select a keypair from the available list. A key pair is a set of security credentials which consists of a public key and a private key. This keypair is used to verify your identity when connecting to an Amazon EC2 instance.
LaunchTemplateVersionNumber	Specify the auto scale group launch template version.
MgmtIPAddress	Specify the comma separated vThunder public management IP addresses.
Role	Specify the existing lambda function IAM Role ARN with lambda function permissions.

Table 12 : JSON Parameters

Resource Name	Description
	To get the value, go to IAM Dashboard > Roles and then click on Iam Role for which you need the ARN.
S3Bucket	Specify the existing S3 bucket name, where the AUTOSCALE_SERVER_PACKAGE.zip is uploaded.
SecurityGroupData	Select the required security group ID from the available list for data interface within the selected Virtual Private Network.
Size	<p>Select an instance/compute type supported for Linux from the available list. A web server is configured on this Linux instance to test traffic. By default, instance type is t2.micro which contains 1 vCPU and 1 GiB memory. The minimum requirement for vThunder is 4 vCPU and 32 GiB memory. For more information on product pricing, see AWS Marketplace.</p> <p>If the required instance type is not available in the list, go to AWS Management Console > EC2 > Launch instance > Find and copy the relevant instance type in the template. For more information, see Supported Instance Types.</p>
SubnetDataID	Select the required subnet ID from the available list for the data traffic flow inward and outward to vThunder within the selected Virtual Private Network.
Zone	Select a zone from the existing availability zones. AWS offers a range of options for managing availability and resiliency for your applications.

Table 12 : JSON Parameters

Resource Name	Description
	NOTE: Make use of the replicated VMs across the availability zones to protect your applications and data against the data center outages and maintenance events.
vThunderSecretManager	Specify the existing secret manager name containing vThunder password. AWS Secret Manager helps you to securely encrypt, store and retrieve credentials for your databases and other services.

- Click **Next**.

The **Configure stack options** window is displayed.

- Verify the other fields and change the values appropriately. (Optional)

- Click **Next**.

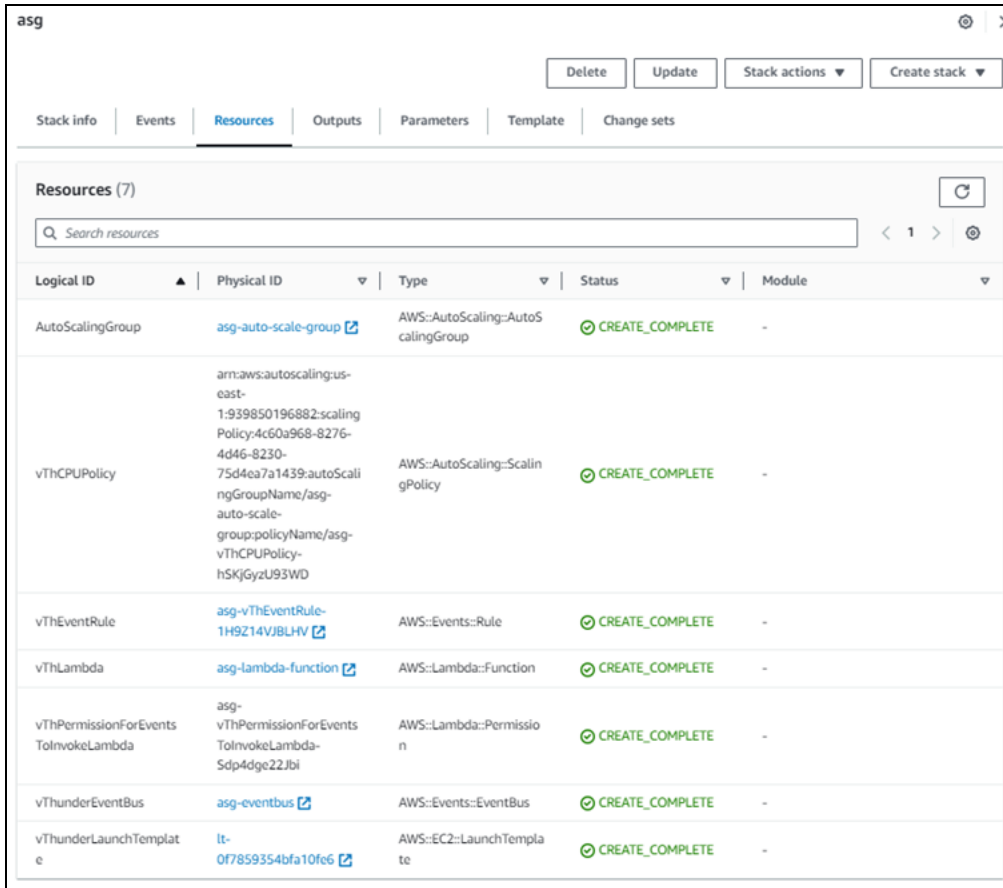

The **Review** `<stack_name>` window is displayed.

- Verify if all the stack configurations are correct and then click **Submit**.

NOTE: The system may take a few minutes to create the resources and display the stack status as **CREATE_COMPLETE**.

- Verify if all the listed resources are created in the **AWS Management Console** > **CloudFormation** > **Stacks** > `<stack_name>` > **Resources** tab:

Figure 37 : Resource listing

Logical ID	Physical ID	Type	Status	Module
AutoScalingGroup	asg-auto-scale-group	AWS::AutoScaling::AutoScalingGroup	CREATE_COMPLETE	-
vThCPUPolicy	arn:aws:autoscaling:us-east-1:939850196882:scalingPolicy:4c60a968-8276-4d46-8230-75d4ea7a1439:autoScalingGroupName/asg-auto-scale-group:policyName/asg-vThCPUPolicy-hSKjGyzU93WD	AWS::AutoScaling::ScalingPolicy	CREATE_COMPLETE	-
vThEventRule	asg-vThEventRule-1H9Z14VJBLHV	AWS::Events::Rule	CREATE_COMPLETE	-
vThLambda	asg-lambda-function	AWS::Lambda::Function	CREATE_COMPLETE	-
vThPermissionForEventsToInvokeLambda	asg-vThPermissionForEventsToInvokeLambda-Sdp4dge22Jbi	AWS::Lambda::Permission	CREATE_COMPLETE	-
vThunderEventBus	asg-eventbus	AWS::Events::EventBus	CREATE_COMPLETE	-
vThunderLaunchTemplate	lt-0f7859354bfa10fe6	AWS::EC2::LaunchTemplate	CREATE_COMPLETE	-

- Verify if the environment variables of the Lambda function are created in **AWS Management Console > Lambda > Functions > <function_name> > Configuration > Environment variables** tab.

Figure 38 : Lambda Function

NOTE: If you delete a stack that contains a Lambda function, the Lambda function will not be deleted automatically along with the stack. You need to manually delete the Lambda function separately. For more information, see [Delete the resources](#).

Configure Lambda Function and ASG

To configure Lambda Function and ASG, perform the following steps:

1. Download **A10-vThunder_ADC-CONFIGURATION > CONFIG-SLB_ON_BACKEND-AUTOSCALE** template from [GitHub](#).
2. From the Start menu, open command prompt and navigate to this downloaded template.
3. Open the AUTOSCALE_SERVER_PARAM.json with a text editor.

NOTE: Each parameter has a default value mentioned in the parameter file which can be modified as required.

4. Configure the following parameters:

Table 13 : JSON Parameters

Resource Name	Description
Desired Capacity	Set the capacity of the autoscale server. <pre>"desiredCapacity": 1,</pre>
Lambda Function	Specify the name of the lambda function. <pre>"lambdaFunction": "lambda-function",</pre>
autoscale Group	Specify the autoscale Group name. <pre>"autoscaleGroupName": "auto-scale-group",</pre>
Port List	Specify the SLB Server ports' details. <pre>"port-list": [{ "port-number": 53, "protocol": "udp" }, { "port-number": 80, "protocol": "tcp" }, { "port-number": 443, "protocol": "tcp" }]</pre>

- Verify if all the configurations in the AUTOSCALE_SERVER_PARAM.json file are correct and save the changes.
- Run the following command to configure the vThunder instance/s as an SLB on

Backend AutoServer:

```
PS C:\Users\TestUser\A10-vThunder_ADC-CONFIGURATION\CONFIG-SLB_ON_
BACKEND-AUTOSCALE> python ./AUTOSCALE_SERVER_ASG_LAMBDA_UPDATE_2.py
```

If SLB is configured successfully, the following message is displayed:

```
Added PortList in asg-lambda environment variables
Updated desired capacity of autoscale group to 1
```

7. Verify the scale-in and scale-out instances in the **AWS Management Console > EC2 > Auto Scaling groups > <asg_name> > Activity** tab.

SSL Certificate

This template applies Certificate Authority SSL Certificate to the vThunder instance. This certificate establishes an encrypted link between the server and your browser, ensuring that all data transferred between them remains private and secure.

To configure SSL certificate for a vThunder instance, perform the following steps:

1. Download **A10-vThunder_ADC-CONFIGURATION > SSL-CERTIFICATE** from [GitHub](#).
2. From the Start menu, open command prompt and navigate to this downloaded template.
3. Open the SSL_CONFIG_PARAM.json with a text editor.

NOTE: Each parameter has a default value mentioned in the parameter file which can be modified as required.

4. Configure the following parameters:

Table 14 : JSON Parameters

Resource Name	Description
Public IP List	Specify the Public IP address of one or more vThunder instance/s and instance ID list (in the same order as public IP) of vThunders to change password.

Table 14 : JSON Parameters

Resource Name	Description
	<pre>"publicIpList": ["X.X.X.X", "X.X.X.X"],</pre>
<p>SSL Configuration</p>	<p>Specify SSL details.</p> <pre>"sslConfig": { "requestTimeout": 40, "path": "server.pem", "file": "server", "certificationType": "pem" }</pre> <hr/> <p>NOTE: By default, SSL configuration is disabled i.e. no SSL configuration is applied.</p> <hr/> <p>Example</p> <p>The sample values for the SSL certificate are as shown below:</p> <pre>"sslConfig": { "requestTimeout": 40, "Path": "C:\\..... \\server.pem", "File": "server", "CertificationType": "pem" }</pre>

5. Verify if the configurations in the SSL_CONFIG_PARAM.json file are correct and then save the changes.
6. Run the following command to apply SSL configuration on the vThunder instance/s:

```
PS C:\Users\TestUser\A10-vThunder_ADC-CONFIGURATION\SSL-CERTIFICATE>
python ./SSL_CONFIG.py
```

7. If the SSL certificate is uploaded successfully, the following message is displayed:

```
Configuring vThunder with ip x.x.x.x
Enter vThunder Password:
Successfully configured SSL.
Configurations are saved on partition: shared
Successfully logged out from vThunder.
```

A10 License

This template applies GLM license to the vThunder instance for legal compliance, security, all feature access, and support.

To configure GLM license for vThunder instance, perform the following steps:

1. Download **A10-vThunder_ADC-CONFIGURATION > GLM-LICENSE** from [GitHub](#).
2. From the Start menu, open command prompt and navigate to this downloaded template.
3. Open the GLM_CONFIG_PARAM.json with a text editor.

NOTE: Each parameter has a default value mentioned in the parameter file, which can be modified as required.

4. Configure the following parameters:

Table 15 : JSON Parameters

Resource Name	Description
Public IP addresses	Specify the Public IP address to apply GLM. <pre>"publicIpList": ["X.X.X.X", "X.X.X.X"],</pre>
DNS	Specify a domain namespace. <pre>"dns": { "value": "8.8.8.8" },</pre>
Entitlement Token	Specify the entitlement token.

Table 15 : JSON Parameters

Resource Name	Description
	<pre>"entitlement_token": { "value": "XXXXXXXXXXXXXXXX" }</pre>

- Verify if the configurations in the GLM_CONFIG_PARAM.json file are correct and then save the changes.
- Run the following command to apply GLM license on the vThunder instance/s:

```
PS C:\Users\TestUser\A10-vThunder_ADC-CONFIGURATION\GLM-LICENSE> python
./GLM_CONFIG.py
```

- Provide password for the vThunder instance/s whose IP address is mentioned in the GLM_CONFIG_PARAM.json file.

```
Configuring vThunder with ip x.x.x.x
Enter vThunder Password:
Successfully configured primary DNS.
Successfully configured GLM Entitlement token in vthunder.
GLM license request sent successfully.
Configurations are saved on partition: shared
Successfully logged out from vThunder.
```

High Availability

This template applies high availability configuration to the Thunder instances. It automatically synchronizes Thunder configurations between the active and standby Thunder instances. In the event of a failover, it designates the other Thunder instance as active to ensure uninterrupted traffic routing. For this functionality, it is essential for both Thunder instances to have identical resources and configurations.

High availability can be configured only within same availability zone in the same region.

Thunder instances should have the same ACOS versions; otherwise, traffic flow will be disrupted.

To configure HA for Thunder instances, perform the following steps:

1. Configure a new or an existing FTP server. For more information, see [Configure the FTP server](#).
2. Download **A10-vThunder_ADC-CONFIGURATION > HIGH-AVAILABILITY** template from [GitHub](#).
3. From Start menu, open command prompt and navigate to this downloaded template.
4. Open the HA_CONFIG_PARAM.json with a text editor.

NOTE: Each parameter has a default value mentioned in the parameter file which can be modified as required.

5. Configure the following parameters:

Table 16 : JSON Parameters

Resource Name	Description
Public IP addresses	Specify the Public IP address of one or more vThunder instance/s depending on the deployed template. <pre>"publicIpList": ["X.X.X.X", "X.X.X.X"],</pre>
Instance IDs	Specify the EC2 instance ID list in the same order as the Public IP addresses. <pre>"instanceIdList": ["XXXXXXXXXX", "XXXXXXXXXX"],</pre> To get the EC2 Instance ID, go to AWS > <region_name> > EC2 > Instances > <instance_id> .
ftpServerName	Specify the name of the FTP server to upload keys. <pre>"ftpServerName": "ftp-server",</pre>
DNS	Specify a domain namespace.

Table 16 : JSON Parameters

Resource Name	Description
	<pre data-bbox="548 365 1414 478"> "dn": { "value": "8.8.8.8" }, </pre>
Network Gateway IP	<p data-bbox="548 504 1414 537">Specify a Network Gateway IP.</p> <p data-bbox="548 569 1414 686">The default value of network gateway IP address is 10.0.1.1 as this is the first IP address of the default management subnet configuration.</p> <p data-bbox="548 718 1414 835">The default value of next network gateway IP address is 10.0.2.1 as this is the first IP address of the data-in subnet configuration.</p> <pre data-bbox="548 867 1414 1438"> "rib-list": [{ "ip-dest-addr": "0.0.0.0", "ip-mask": "/0", "ip-nexthop-ipv4": [{ "ip-next-hop": "10.0.1.1" }, { "ip-next-hop": "10.0.2.1" }] }], </pre>
VRRP-A	<p data-bbox="548 1463 1414 1497">Specify the value as 1 to enable VRRP-A.</p> <pre data-bbox="548 1528 1414 1642"> "vrrp-a": { "set-id": 1 }, </pre>
Terminal Idle Timeout	<p data-bbox="548 1667 1414 1738">Specify the interval in minutes for closing connection when there is no input detected. The value '0' means never</p>

Table 16 : JSON Parameters

Resource Name	Description
	<p>timeout.</p> <pre> "terminal": { "idle-timeout":0 }, </pre>
VRID details	<p>Specify the VRID details.</p> <p>The default value of vrid is 0. The default priority for the first vThunder instance is 100, and for second the vThunder is 99 (100-1).</p> <pre> "vrid-list": [{ "vrid-val": 0, "blade-parameters": { "priority": 100 } }] </pre>

- Verify if all the configurations in the HA_CONFIG_PARAM.json file are correct and save the changes.
- Import AWS access key on both the vThunder instances. For more information, refer [Import the AWS Access Keys](#).
- Run the following command to configure HA:

```
PS C:\Users\TestUser\A10-vThunder_ADC-CONFIGURATION\HIGH-AVAILABILITY>
python ./HA_CONFIG.py
```

- Provide password for the vThunder instances/s whose IP address is mentioned in the HA_CONFIG_PARAM.json file.
If HA is configured successfully, the following message is displayed:

```
Configuring vThunder with ip x.x.x.x
Enter vThunder password: *****
Successfully uploaded AWS access keys to vThunder
Successfully configured Primary DNS.
Successfully configured IP Route.
Successfully configured Vrrp-A Common.
Successfully configured Idle Timeout.
Successfully configured Vrrp Rid.
Successfully configured Peer Group.
Configurations are saved on partition: shared
Successfully logged out from vThunder.

High Availability Across Availability Zones

This template applies high availability configuration to the Thunder instances in the same availability zone having interface in different subnet or across different availability zones. It automatically synchronizes Thunder configurations between the active and standby Thunder instances. In the event of a failover, it designates the other Thunder instance as active to ensure uninterrupted traffic routing. For this functionality, it is essential for both Thunder instances to have identical resources and configurations.

Thunder instances should have the same ACOS versions; otherwise, traffic flow will be disrupted.

To configure HA Across AZs for Thunder instances, perform the following steps:

1. Configure a new or an existing FTP server. For more information, see [Configure the FTP server](#).
Alternatively, from ACOS 6.0.5 onwards, you can attach an IAM role to the Thunder device, which can be used to fetch the AWS access key and secret key.
2. Download **A10-vThunder_ADC-CONFIGURATION > HIGH-AVAILABILITY-ACROSS-AZs** template from [GitHub](#).
3. From Start menu, open command prompt and navigate to this downloaded template.
4. Open the HA_Across_AZs_CONFIG_PARAM.json with a text editor.

NOTE: Each parameter has a default value mentioned in the parameter file which can be modified as required.

5. Configure the following parameters:

Table 17 : JSON Parameters

Resource Name	Description
Instance IDs	Specify the EC2 instance ID list in the same order as the Public IP addresses. <pre>"instanceIdList": ["XXXXXXXXXX", "XXXXXXXXXX"],</pre> <p>To get the EC2 Instance ID, go to AWS > <region_name> > EC2 > Instances > <instance_id>.</p>
ftpServerName	Specify the name of the FTP server to upload keys. <pre>"ftpServerName": "ftp-server",</pre>
DNS	Specify a domain namespace. <pre>"dns": { "value": "8.8.8.8" },</pre>
Network	Specify a Network Gateway IP of active vThunder instance.

Table 17 : JSON Parameters

Resource Name	Description
Gateway IP for Active vThunder	<p>The gateway IP is the first IP address of the management subnet, such as 10.0.1.1 in the configuration.</p> <p>You can configure multiple network gateway IPs for different routing paths.</p> <pre data-bbox="548 579 1419 1409">"rib-list_active": [{ "ip-dest-addr": "0.0.0.0", "ip-mask": "/0", "ip-next-hop-ipv4": [{ "ip-next-hop": "10.0.1.1" }] }, { "ip-dest-addr": "10.0.8.0", "ip-mask": "/24", "ip-next-hop-ipv4": [{ "ip-next-hop": "10.0.3.1" }] }]</pre>
Network Gateway IP for Standby vThunder	<p>Specify a Network Gateway IP of standby vThunder instance.</p> <p>The gateway IP is the first IP address of the management subnet, such as 10.0.1.1 in the configuration.</p> <p>You can configure multiple network gateway IPs for different routing paths.</p>

Hybrid Cloud GSLB

A hybrid cloud configuration as a Global Server Load balancer (GSLB) between two regions residing in the same or different cloud or on-premise environments. It provides flexibility to implement disaster recovery site.

It requires atleast two Thunder instances in each region or location. One instance serves as the master controller, while the other functions as the site device. It is possible to configure multiple site devices, but it is recommended to have a minimum of three site devices to ensure seamless failover and effective disaster recovery.

Both regions should maintain an equivalent number of resources, whether hosted in the cloud or on-premise.

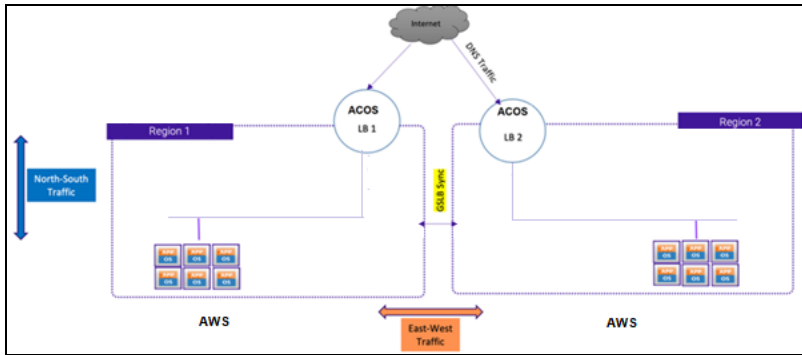

To create and install three thunder instances in any one region use [Thunder-3NIC-3VM](#) template. The same template can be used to install Thunder instances in another region.

Architectural References

Refer to the following for architectural references:

- AWS-to-AWS
Region 1 and Region 2 both are in AWS cloud.

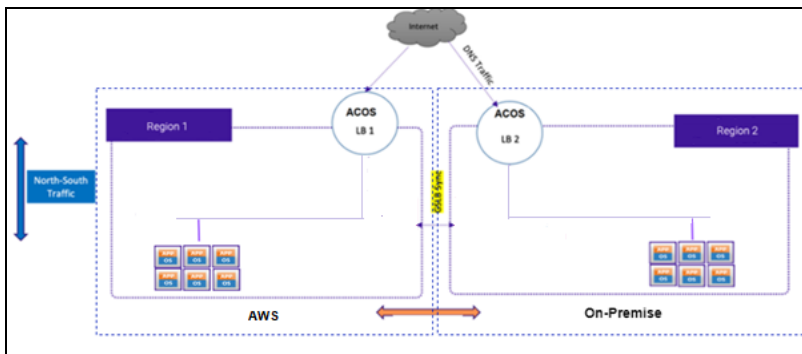

Figure 39 : AWS-to-AWS Cloud

- AWS-to-On-Premises (any)

Region 1 is in AWS cloud and Region 2 is on-premise or vice versa.

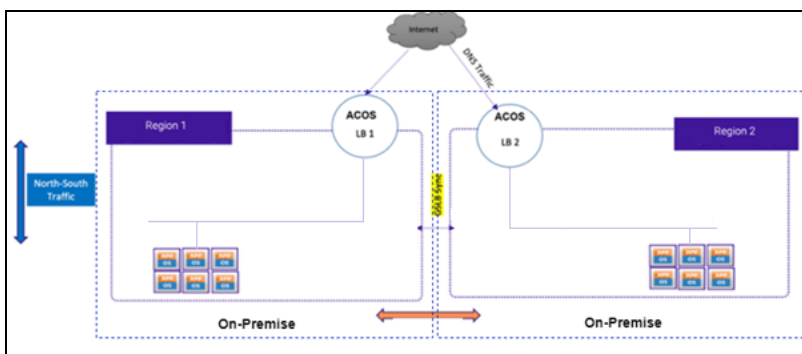

Figure 40 : AWS-to-On-Premise

- On-Premise-to-On-Premise (any)

Region 1 and Region 2 are on-premises.

Figure 41 : On-Premise-to-On-Premise

GSLB Deployment Topology

[Figure 42](#) shows the GSLB deployment topology having two regions, Region 1 and Region 2. Both the regions must have identical number of resources:

- One GSLB controller
This Thunder instance acts as a DNS server that directs clients to reach the active load balancer.
GSLB controller of Region 1 is considered as the 'Master' and Region 2 is considered as a 'Member'.
- Two site devices
These Thunder instances act as a load balancer and send traffic to the server.
Each site device may have multiple app or web servers configured and route the traffic accordingly.

Figure 42 : Hybrid Cloud GSLB Deployment Topology

Configure Hybrid Cloud GSLB

A Hybrid Cloud GSLB configuration requires two regions and each region should host three Thunder instances.

To configure hybrid cloud GSLB, perform the following:

1. Create three vThunder instances if not already created. For more information, see [Thunder-3NIC-3VM](#).
2. Download **A10-vThunder_ADC-CONFIGURATION > HYBRID-CLOUD-GSLB** folder from [GitHub](#).
3. From the Start menu, open the command prompt and navigate to the downloaded template.
4. Open the HYBRID_CLOUD_CONFIG_GSLB_PARAM.json with a text editor.

NOTE: Each parameter has a default value mentioned in the parameter file which can be modified as required.

5. Configure the following parameters:

Table 18 : JSON Parameters

Resource Name	Description
Master Controller	Specify the Master Controller Parameter Details for Region 1. Master Controller is the first vThunder instance in Region 1 and it could be any vThunder instance.

Table 18 : JSON Parameters

Resource Name	Description
	<pre> "masterConfigDetails":{ "controllerMngmtPublicIp":"Public IP of Management Interface of Location1 Controller", "controllerPassword":"vThunder's Login password of Location1 Controller", "controllerSecPrivateIpData1":"Secondary Pvt IP of DataSubnet1 of Location1 Controller", "site1MngmtPublicIp":"Public IP of Management Interface of Location1 Site1", "site1Password":"vThunder's Login password of Location1 Site1 vThunder", "site2MngmtPublicIp":"Public IP of Management Interface of Location1 Site2", "site2Password":"vThunder's Login password of Location1 Site2 vThunder", "site1SecPrivateIpData1":"Secondary Pvt IP of DataSubnet1 of Location1 Site1 vThunder", "site1SecPublicIpData1":"Secondary Public IP of DataSubnet1 of Location1 Site1 vThunder", "site2SecPrivateIpData1":"Secondary Pvt IP of DataSubnet1 of Location1 Site2 vThunder", "site2SecPublicIpData1":"Secondary Public IP of DataSubnet1 of Location1 Site2 vThunder", "server1PrivateIp":"Private Ipv4 address of server1 of Location1", "server2PrivateIp":"Private Ipv4 address of server2 of Location1" }, </pre>
Member Controller	<p>Specify the Member Controller Parameter Details for Region 2.</p> <p>Member Controller is the first vThunder instance in Region 2 and it could be any vThunder instance.</p>

Table 18 : JSON Parameters

Resource Name	Description
	<pre> "memberConfigDetails":{ "controllerMngmtPublicIp":"Public IP of Management Interface of Location2 Controller", "controllerPassword":"vThunder's Login password of Location2 Controller", "controllerSecPrivateIpData1":"Secondary Pvt IP of DataSubnet1 of Location2 Controller", "site1MngmtPublicIp":"Public IP of Management Interface of Location2 Site1", "site1Password":"vThunder's Login password of Location2 Site1 vThunder", "site2MngmtPublicIp":"Public IP of Management Interface of Location2 Site2", "site2Password":"vThunder's Login password of Location2 Site2 vThunder", "site1SecPrivateIpData1":"Secondary Pvt IP of DataSubnet1 of Location2 Site1 vThunder", "site1SecPublicIpData1":"Secondary Public IP of DataSubnet1 of Location2 Site1 vThunder", "site2SecPrivateIpData1":"Secondary Pvt IP of DataSubnet1 of Location2 Site2 vThunder", "site2SecPublicIpData1":"Secondary Public IP of DataSubnet1 of Location2 Site2 vThunder", "server1PrivateIp":"Private Ipv4 address of server1 of Location2", "server2PrivateIp":"Private Ipv4 address of server2 of Location2" }, </pre>
SLB Server Ports	Specify the SLB server ports for site devices.

Table 18 : JSON Parameters

Resource Name	Description
	<pre> "slbServerPortList1": { "value": [{ "port-number": 80, "protocol": "tcp", "health-check-disable":1 }] }, "slbServerPortList2": { "value": [{ "port-number": 80, "protocol": "tcp", "health-check-disable":1 }] }, "slbServerPortList3": { "value": [{ "port-number": 80, "protocol": "tcp", "health-check-disable":1 }] }, "slbServerPortList4": { "value": [{ "port-number": 80, "protocol": "tcp", "health-check-disable":1 }] }, </pre>

Table 18 : JSON Parameters

Resource Name	Description
Service Group	Specify the SLB Service groups for site devices.

Table 18 : JSON Parameters

Resource Name	Description
	<pre>"serviceGroupList1": { "value": [{ "name": "sg", "protocol": "tcp", "health-check-disable": 0, "member-list": [{ "port": 80 }] }] }, "serviceGroupList2": { "value": [{ "name": "sg", "protocol": "tcp", "health-check-disable": 0, "member-list": [{ "port": 80 }] }] }, "serviceGroupList3": { "value": [{ "name": "sg", "protocol": "tcp", "health-check-disable": 0, "member-list": [{ "port": 80 }] }] },</pre>

Table 18 : JSON Parameters

Resource Name	Description
Virtual Server	Specify the SLB virtual server for site devices. The virtual server default name is “vs1”.

Table 18 : JSON Parameters

Resource Name	Description

Appendix

Access Thunder Virtual Machine

vThunder instance/s can be accessed using any of the following ways:

- [Access vThunder using CLI](#)
- [Access vThunder using GUI](#)

Access vThunder using CLI

To access vThunder instance/s using CLI, perform the following steps:

1. From **AWS Management Console**, navigate to **EC2 > Instances**.
2. Select the vThunder instance name/s depending on your deployment template.

Figure 43 : 2NIC-1VM vThunder instance

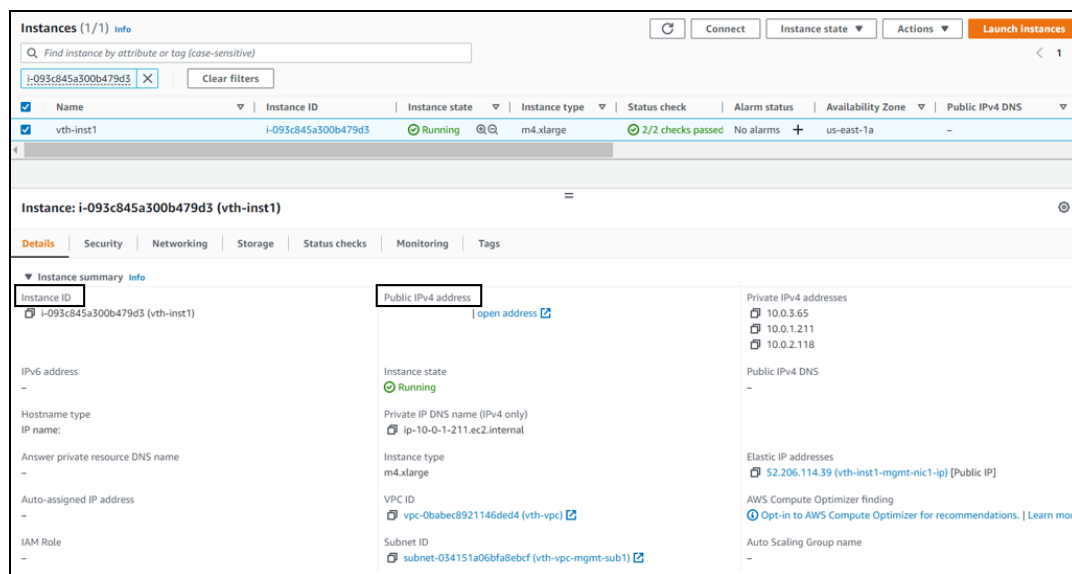

Table 23 : Sample vThunder instance name/s

CFT Template	vThunder Instance
Thunder-2NIC-1VM	<code>vth-inst1</code>

Table 23 : Sample vThunder instance name/s

CFT Template	vThunder Instance
Thunder-3NIC-2VM	vth-inst1
	vth-inst2
Thunder-3NIC-3VM	vth-rg1-inst1
	vth-rg1-inst2
	vth-rg1-inst3
	vth-rg2-inst1
	vth-rg2-inst2
	vth-rg2-inst3

3. For one or more vThunder instance, perform the following steps:
 - a. Copy the **Public IPv4 address** from the **Details** tab.
 - b. Open any SSH client and provide the following details to establish a connection:
 - Hostname: Public IPv4 address
 - Username: admin
 - Key: SSH Key
 - c. Connect to the session.
 - d. In the SSH client session, run the following commands:

```
vThunder (NOLICENSE) >enable <---Execute command--->
Password:                <---just press Enter key--->
vThunder (NOLICENSE) #config <---Configuration mode--->
vThunder (config) (NOLICENSE) #
```

The vThunder instance/s are ready to use.

Access vThunder using GUI

To access vThunder instance/s using GUI, perform the following steps:

1. From **AWS Management Console**, navigate to **EC2 > Instances**.
2. Select your instance name.

Figure 44 : 2NIC-1VM vThunder instance

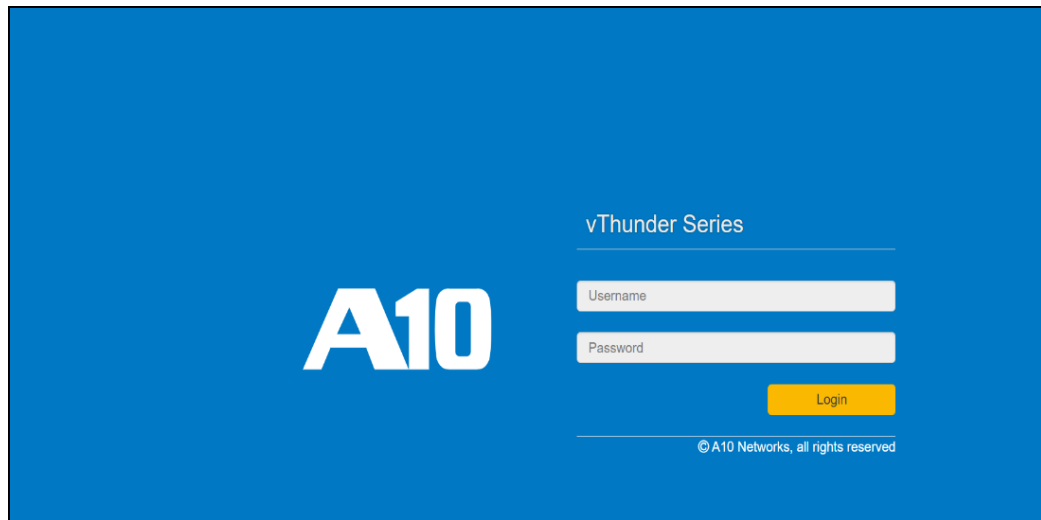

Table 24 : Sample vThunder instance name/s

CFT Template	vThunder Instance
Thunder-2NIC-1VM	vth-inst1
Thunder-3NIC-2VM	vth-inst1
	vth-inst2
Thunder-3NIC-3VM	vth-rg1-inst1
	vth-rg1-inst2
	vth-rg1-inst3
	vth-rg2-inst1
	vth-rg2-inst2
	vth-rg2-inst3

3. For one or more vThunder instance, perform the following steps:
 - a. Copy the **Public IPv4 address** from the **Details** tab and replace the IP address in the below link:
`http://<vThunder_public_IPv4_address>`
 - b. Open the updated link in any browser.
The vThunder login window is displayed.

Figure 45 : vThunder GUI

- c. Enter the following credentials and click **Login**:
 - Username – **admin**
 - Password – *EC2 Instance ID*

The home page is displayed if the entered credentials are correct.

Create Server Machine

A server machine must be created and configured to test the traffic flow via vThunder.

To create and configure a server machine, perform the following steps:

1. From **AWS Management Console**, navigate to **EC2 > Instances**.
2. Click **Launch Instances**.
A **Launch an instance** window is displayed.
3. In the **Name and tags** section, enter an instance name.
Here, enter `server1` as the server instance name.
4. In the **Application and OS Images** section, select **Ubuntu**.
5. In the **Instance type** section, select the required instance type.
6. In the **Key pair (login)** field, select your SSH key.
7. In the **Network settings** section, click **Edit** to edit the following:
 - VPC: *your VPC*
Here, enter `vpc` as the VPC.
 - Subnet: Enter value depending on your template.

Table 25 : Subnet names

CFT Template	Subnet name
Thunder-2NIC-1VM	Data subnet 10.0.2.0/24
Thunder-3NIC-2VM	Data subnet 2 10.0.3.0/24
Thunder-3NIC-3VM	Data subnet 2 10.0.3.0/24

- Auto-assign public IP: Enable
 - Firewall (security groups): Select existing security group
 - Common security groups: *your data security group*
Here, `vpc-vThunderSecurityGroupData` is the security group.
8. Click **Launch instance**.

NOTE: The system may take a few minutes to launch the instance.

The server instance is displayed in the **Instances** list with the status as **Running**.

9. Click **Connect**.

A **Connect to instance** window with **EC2 Instance Connect** tab is displayed.

10. Click **Connect**.

A **Terminal** window is displayed.

11. Run the following commands in the Terminal window to update all the package information:

```
sudo apt update
```

12. Run the following command in the Terminal window to create an Apache Server virtual machine:

```
sudo apt install apache2
```

While the Apache server is getting installed, you get a prompt to continue further. Enter 'Y' to continue. After the installation is complete, a newline prompt is displayed.

13. If you want to configure HTTP template, perform the following steps:

- a. SSH the Apache Server and run the following command:

```
sudo vim /etc/apache2/apache2.conf
```

The Apache2 configuration file is displayed.

- b. Add the following configuration and save the file:

```
Alias /<url-match-string> /var/www/html
```

- c. Restart the Apache server to enable the HTTP service.

```
sudo systemctl restart apache2
```

The server may take a few minutes to restart.

Create Client Machine

A client machine must be created and configured to test the traffic flow via vThunder.

To create and configure a client machine, perform the following steps:

1. From the **AWS Management Console**, navigate to **EC2 > Instances**.
2. Click **Launch Instances**.
A **Launch an instance** window is displayed.
3. In the **Name and tags** section, enter an instance name.
Here, enter `client1` as the client instance name.
4. In the **Application and OS Images** section, select **Ubuntu**.
5. In the **Instance type** section, select the required instance type.
6. In the **Key pair (login)** field, select your SSH key.
7. In the **Network settings** section, click **Edit** to edit the following:
 - VPC: *your VPC*
Here, enter `vpc` as the VPC.
 - Subnet: Enter value depending on your template.

Table 26 : Subnet names

CFT Template	Subnet name
Thunder-2NIC-1VM	Data subnet 10.0.2.0/24
Thunder-3NIC-2VM	Data subnet 2 10.0.3.0/24
Thunder-3NIC-3VM	Data subnet 2 10.0.3.0/24

- Auto-assign public IP: Enable
 - Firewall (security groups): Select existing security group
 - Common security groups: *your data security group*
Here, `vpc-vThunderSecurityGroupData` is the security group.
8. Click **Launch instance**.

NOTE: The system may take a few minutes to launch the instance.

The client instance is displayed in the **Instances** list with the status as **Running**.

Create Virtual Private Cloud

The VPC-SUBNET-NSG template is used to create virtual private cloud (VPC) containing three new subnets and two new security groups (SGs) in the same availability zones.

It is not mandatory to create new resources, the existing resources can be used in deployment and configuration.

If a Security group already exists, it should have the inbound rules as mentioned in [Table 27](#) and [Table 28](#); otherwise, traffic flow will be disrupted.

Table 27 : Management security rules

Security Rule	Protocol	Port
Custom TCP	TCP	4149
SSH	TCP	22
HTTPS	TCP	443
ALL ICMP -IPv4	ICMP	ALL
HTTP	TCP	80
Custom UDP	UDP	161
Custom TCP	TCP	123

Table 28 : Data security rules

Security Rule	Protocol	Port
Custom TCP	TCP	4149
SSH	TCP	22
HTTPS	TCP	443
ALL ICMP -IPv4	ICMP	ALL
HTTP	TCP	80
ALL UDP	UDP	0-65535

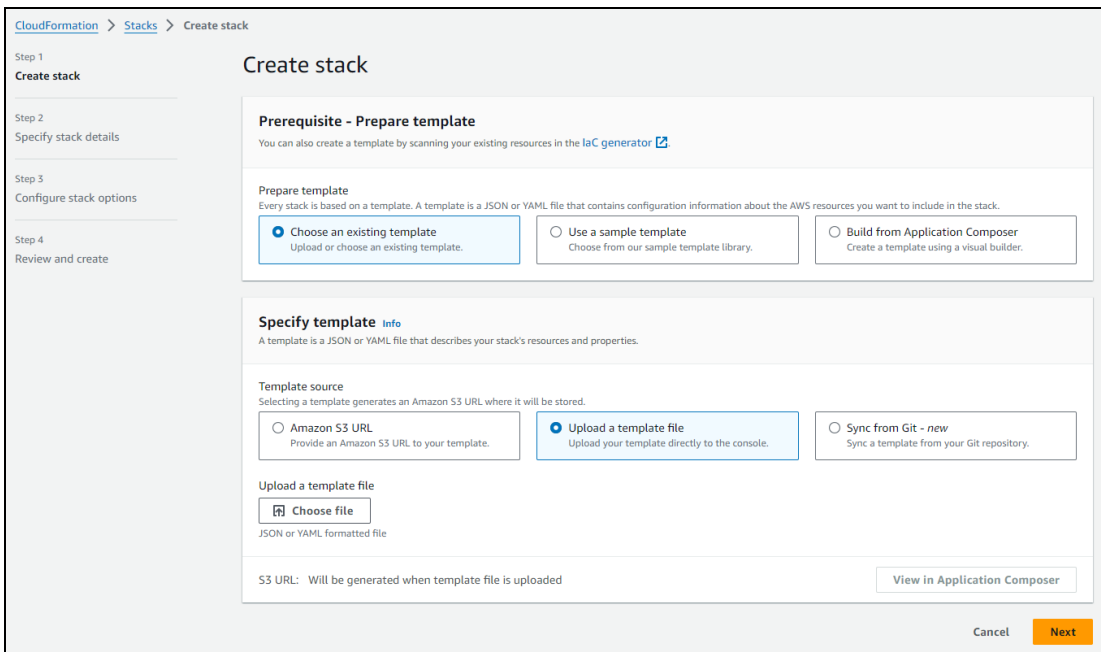

Before deploying this template, it is recommended to review the [Prerequisites](#).

To create Virtual Private Cloud in same availability zone, perform the following steps:

1. Download **A10-vThunder_CFT-TEMPLATES > VPC-SUBNET-NSG** template from [GitHub](#).
2. From AWS Management Console, navigate to **CloudFormation > Stacks > Create Stack > With new resources (standard)**.

The Create stack window is displayed.

Figure 46 : Create stack window

3. In the **Prerequisite - Prepare template** section, select **Choose an existing template**.

After selecting this option, the Specify template section is displayed.

4. In the **Specify template** section, select **Upload a template file** and click **Choose file** to browse and upload the following template file from the downloaded CFT folder:

CFT_TMPL_VIRTUAL_PRIVATE_COMPONENTS.json

The selected template file name is displayed as the chosen file.

5. Click **Next**.

The **Specify stack details** window is displayed.

Figure 47 : Specify stack details window

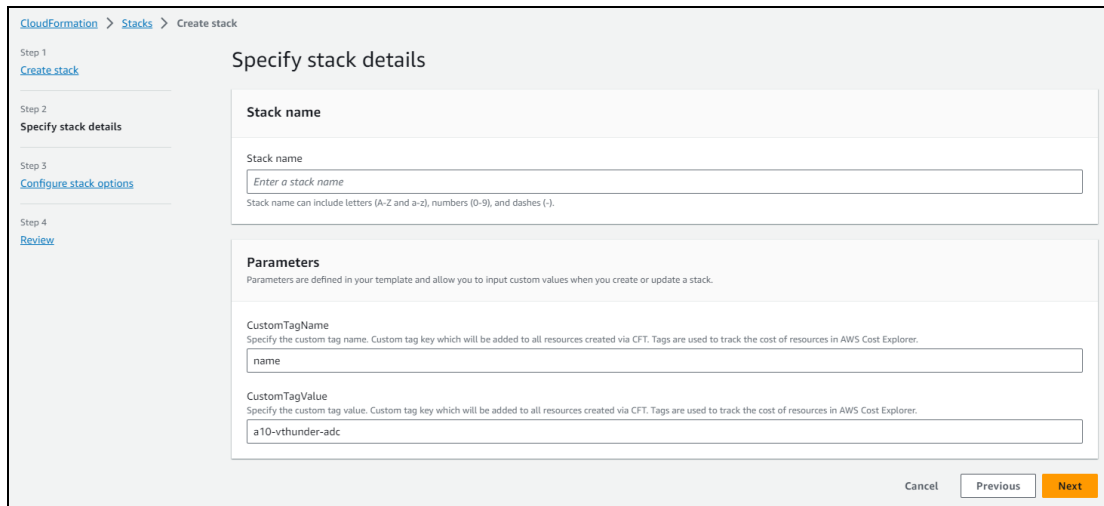

6. In the **Specify stack details** window, enter or select the following:

Table 29 : JSON Parameters

Resource Name	Description
Stack name	Specify a stack name containing letters (A-Z and a-z), numbers (0-9), and dashes (-). Here, the stack name is provided as <code>vpc</code> .
CidrDataSubnetIn	Specify the Classless Inter-Domain Routing (CIDR) of the data-in subnet.
CidrDataSubnetOut	Specify the CIDR of the data-out Subnet.
CidrMgmtSubnet	Specify the CIDR of the Management Subnet.
CidrVPC	Specify the IPv4 CIDR of the VPC. The allowed block size is between a /16 netmask (65,536 IP addresses) and /28 netmask (16 IP addresses).
CustomTagName	Specify the custom tag name. The custom tag key is added to all the resources created using the CFT template. This tag is used to track the cost of resources

Table 29 : JSON Parameters

Resource Name	Description
	in the AWS Cost Explorer.
CustomTagValue	Specify the custom tag value. The custom tag key is added to all the resources created using the CFT template. This tag is used to track the cost of resources in the AWS Cost Explorer. The default custom tag value is a10-vthunder-adc .
Zone	Select the existing availability zones. AWS offers a range of options for managing availability and resiliency for your applications. NOTE: Architect your solution to use the replicated VMs across the availability zones to protect your applications and data against the datacenter outages and maintenance events.

- Click **Next**.

The **Configure stack options** window is displayed.

- Verify the other fields and change the values appropriately. (Optional)
- Click **Next**.

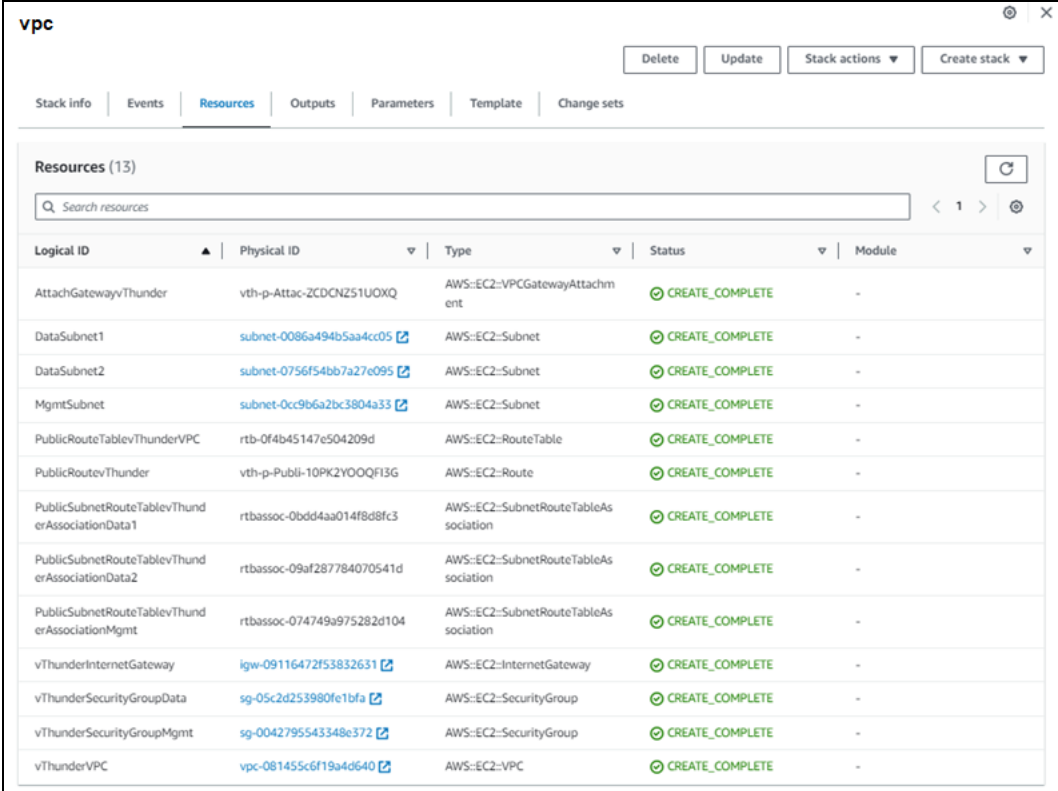

The **Review** `<stack_name>` window is displayed.

- Verify if all the stack configurations are correct and then click **Submit**.

NOTE: The system may take a few minutes to create the resources and display the stack status as **CREATE_COMPLETE**.

- Verify if the elastic IPs are created in the **AWS Management Console** > **CloudFormation** > **Stacks** > `<stack_name>` > **Resources** tab.

Create Virtual Private Cloud for Different Availability Zones

The VPC-SUBNET-NSG template is used to create virtual private cloud (VPC) containing six new subnets and two new security groups (SGs) across different availability zones.

It is not mandatory to create new resources, the existing resources can be used in deployment and configuration.

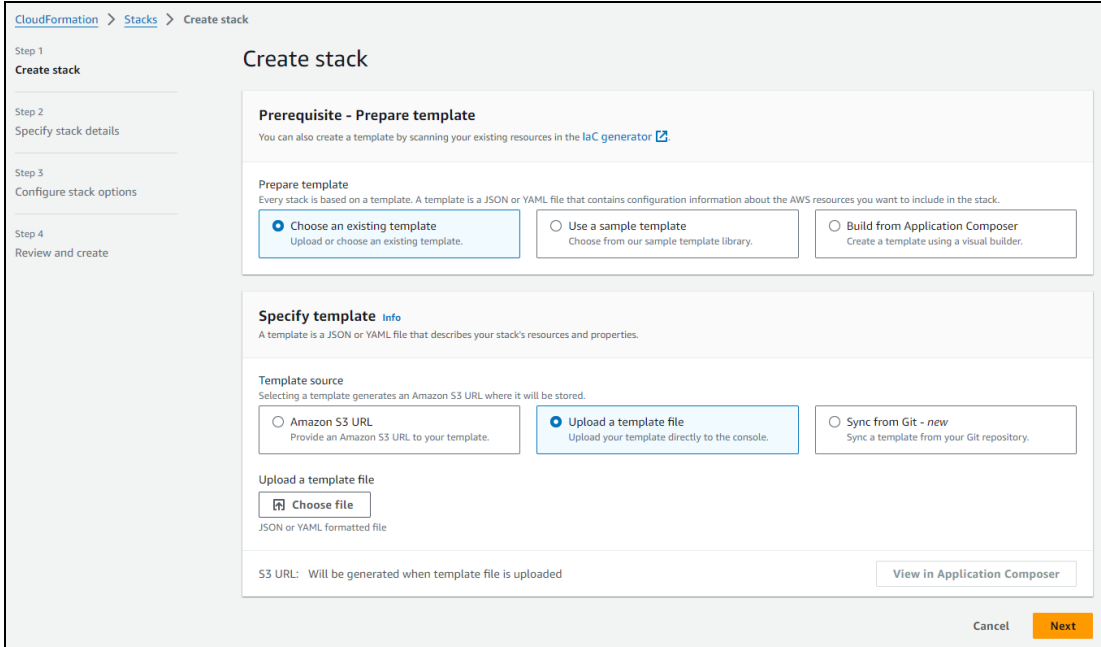

Before deploying this template, it is recommended to review the [Prerequisites](#).

To create Virtual Private Cloud for different availability zones, perform the following steps:

1. Download **A10-vThunder_CFT-TEMPLATES > VPC-SUBNET-NSG** template from [GitHub](#).
2. From AWS Management Console, navigate to **CloudFormation > Stacks > Create Stack > With new resources (standard)**.

The Create stack window is displayed.

Figure 49 : Create stack window

3. In the **Prerequisite - Prepare template** section, select **Choose an existing template**.

After selecting this option, the Specify template section is displayed.

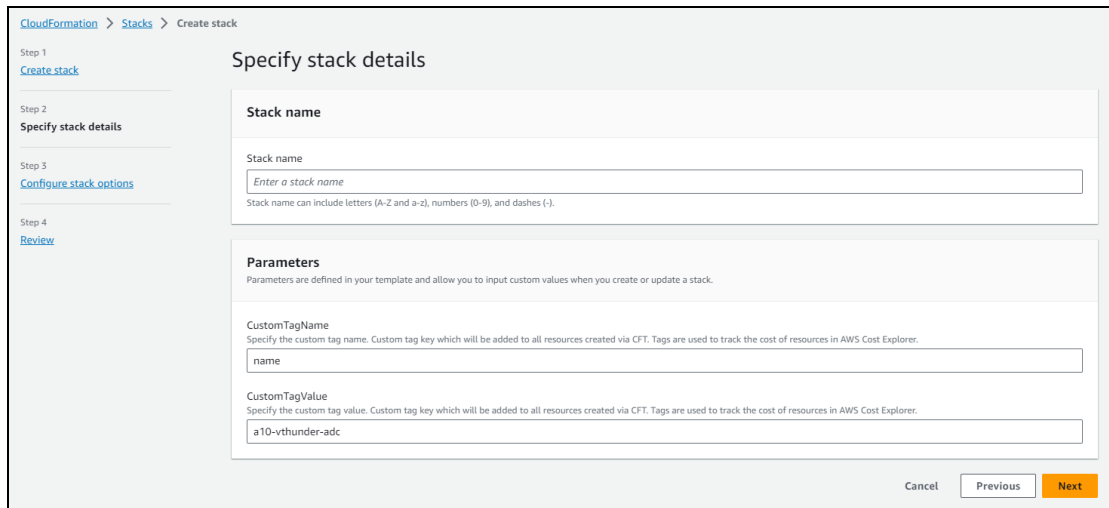

4. In the **Specify template** section, select **Upload a template file** and click **Choose file** to browse and upload the following template file from the downloaded CFT folder:
CFT_TMPL_VIRTUAL_PRIVATE_COMPONENTS_Across_AZ_HA.json

The selected template file name is displayed as the chosen file.

5. Click **Next**.

The **Specify stack details** window is displayed.

Figure 50 : Specify stack details window

6. In the **Specify stack details** window, enter or select the following:

Table 30 : JSON Parameters

Resource Name	Description
Stack name	Specify a stack name containing letters (A-Z and a-z), numbers (0-9), and dashes (-). Here, the stack name is provided as vpc .
CidrDataInSubnetActiveThunder	Specify the Classless Inter-Domain Routing (CIDR) of the Active Data-In Subnet.
CidrDataInSubnetStandByThunder	Specify the CIDR of the StandBy Data-In Subnet.
CidrDataOutSubnetActiveThunder	Specify the CIDR of the Active Data-Out Subnet.
CidrDataOutSubnetStandByThunder	Specify the CIDR of the StandBy Data-Out Subnet.
CidrMgmtSubnetActiveThunder	Specify the CIDR of the Active Management Subnet.
CidrMgmtSubnetStandByThunder	Specify the CIDR of the StandBy

Table 30 : JSON Parameters

Resource Name	Description
	Management Subnet.
CidrVPC	Specify the IPv4 CIDR of the VPC. The allowed block size is between a /16 netmask (65,536 IP addresses) and /28 netmask (16 IP addresses).
CustomTagName	Specify the custom tag name. The custom tag key is added to all the resources created using the CFT template. This tag is used to track the cost of resources in the AWS Cost Explorer.
CustomTagValue	Specify the custom tag value. The custom tag key is added to all the resources created using the CFT template. This tag is used to track the cost of resources in the AWS Cost Explorer. The default custom tag value is a10-vthunder-adc .
DifferentAvailabilityZone	Select Yes if you want to deploy your vThunder instances across different availability zones. The default set value is No .
ZoneActiveThunder	Select from the existing availability zones for active vThunder instance. NOTE: Architect your solution to use the replicated VMs across the availability zones to protect your applications and data against the datacenter outages and maintenance events.

Table 30 : JSON Parameters

Resource Name	Description
ZoneStandByThunder	<p>Select from the existing availability zones for standby vThunder instance.</p> <p>NOTE: Architect your solution to use the replicated VMs across the availability zones to protect your applications and data against the datacenter outages and maintenance events.</p>

7. Click **Next**.

The **Configure stack options** window is displayed.

8. Verify the other fields and change the values appropriately. (Optional)
9. Click **Next**.

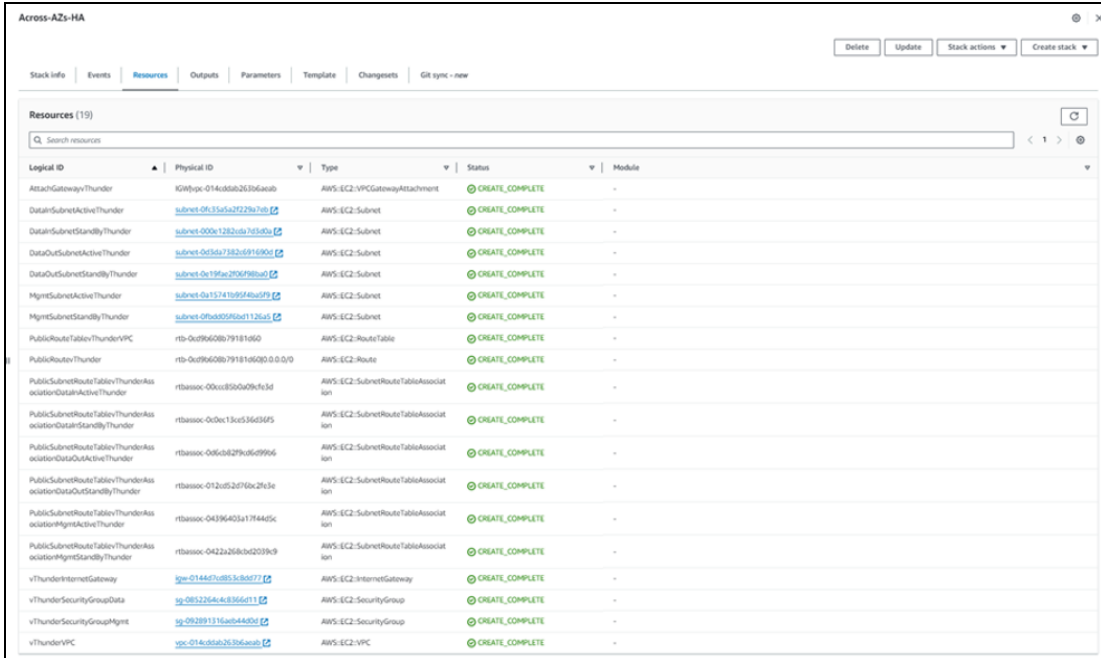

The **Review** *<stack_name>* window is displayed.

10. Verify if all the stack configurations are correct and then click **Submit**.

NOTE: The system may take a few minutes to create the resources and display the stack status as **CREATE_COMPLETE**.

11. Verify if the elastic IPs are created in the **AWS Management Console** > **CloudFormation** > **Stacks** > *<stack_name>* > **Resources** tab.

Create Elastic Public IP

The PUBLIC-IP template is used to create three new elastic public IP addresses.

It is not mandatory to create new resources, the existing resources can be used in deployment and configuration.

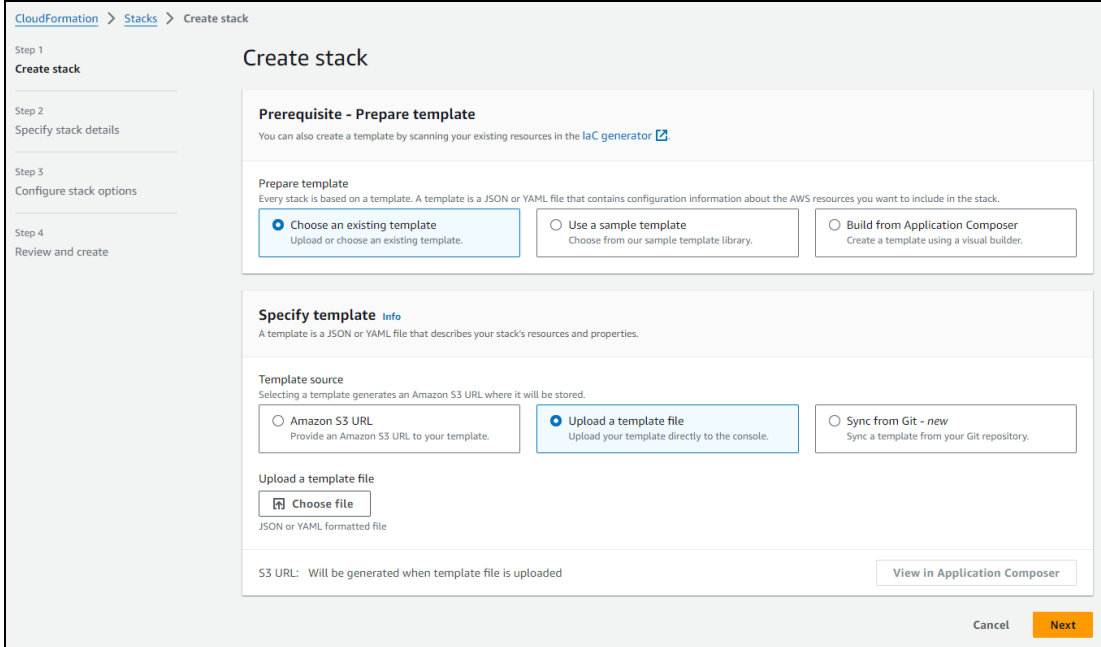

Before deploying this template, it is recommended to review the [Prerequisites](#).

To create Elastic Public IP, perform the following steps:

1. Download **A10-vThunder_CFT-TEMPLATES > PUBLIC-IP** template from [GitHub](#).
2. From the **AWS Management Console**, navigate to **CloudFormation > Stacks > Create Stack > With new resources (standard)**.

The Create stack window is displayed.

Figure 52 : Create stack window

3. In the **Prerequisite - Prepare template** section, select **Choose an existing template**.

After selecting this option, the Specify template section is displayed.

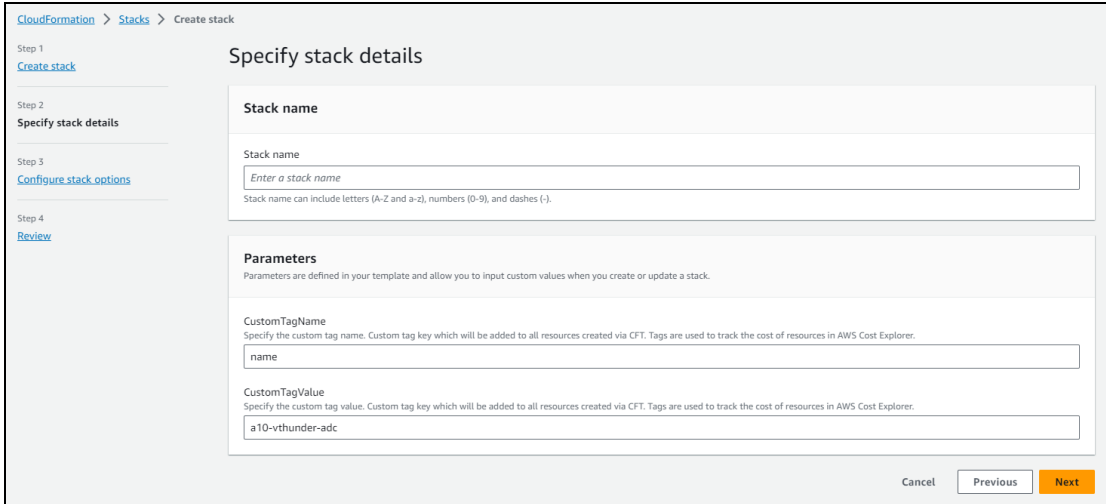

4. In the **Specify template** section, select **Upload a template file** and click **Choose file** to browse and upload the following template file from the downloaded CFT folder:
CFT_TMPL_ELASTIC_PUBLIC_IP.json

The selected template file name is displayed as the chosen file.

5. Click **Next**.

The **Specify stack details** window is displayed.

Figure 53 : Specify stack details window

6. In the **Specify stack details** window, enter or select the following:

Table 31 : JSON Parameters

Resource Name	Description
Stack name	Specify a stack name containing letters (A-Z and a-z), numbers (0-9), and dashes (-). Here, the stack name is provided as eip .
CustomTagName	Specify the custom tag name. The custom tag key is added to all the resources created using the CFT template. This tag is used to track the cost of resources in the AWS Cost Explorer.
CustomTagValue	Specify the custom tag value. The custom tag key is added to all the resources created using the CFT template. This tag is used to track the cost of resources in the AWS Cost Explorer. The default custom tag value is a10-vthunder-adc .

7. Click **Next**.

The **Configure stack options** window is displayed.

8. Verify the other fields and change the values appropriately. (Optional)

9. Click **Next**.

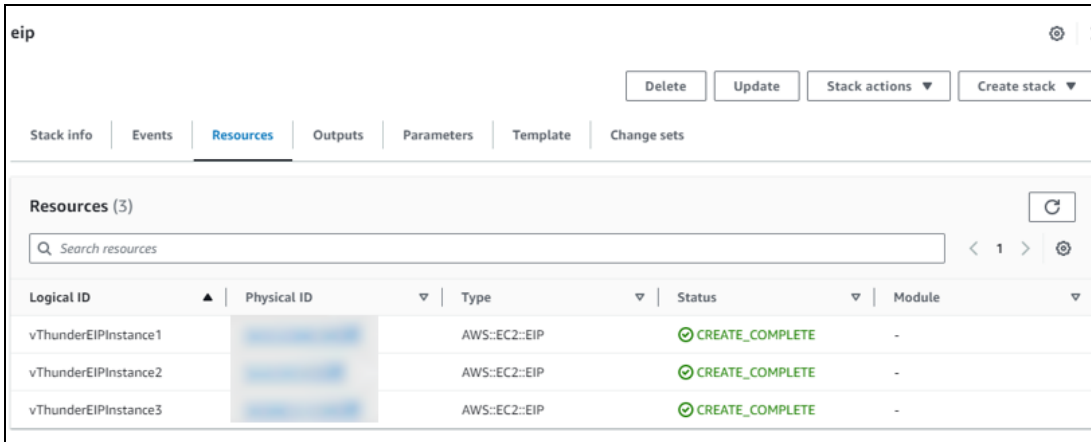

The **Review** `<stack_name>` window is displayed.

10. Verify if all the stack configurations are correct and then click **Submit**.

NOTE: The system may take a few minutes to create the resources and display the stack status as **CREATE_COMPLETE**.

11. Verify if the elastic IPs are created in the **AWS Management Console** > **CloudFormation** > **Stacks** > `<stack_name>` > **Resources** tab.

Figure 54 : Resource listing

Logical ID	Physical ID	Type	Status	Module
vThunderEIPInstance1		AWS::EC2::EIP	CREATE_COMPLETE	-
vThunderEIPInstance2		AWS::EC2::EIP	CREATE_COMPLETE	-
vThunderEIPInstance3		AWS::EC2::EIP	CREATE_COMPLETE	-

Default Password Policy

The default password policy has the following criteria:

- The password should be at least nine characters in length.
- The password should contain at least one number, an uppercase letter (English), a lowercase letter (English), and a special character.
- The password should have at least one letter or number different from the previous password.
- The password should not contain its corresponding username with the same capitalization of letters.

- The password should not contain repeated characters of the same letter or number with the same capitalization of letters.
- The password should not contain the sequential row keyboard input of four letters or numbers with the same capitalization of letters.

Configure the FTP server

In a High Availability (HA) configuration, IP switching occurs between two vThunder instances. The IP switching is enabled when AWS keys are imported on the vThunder instances using the FTP server. You can configure an existing FTP server or create a new one.

Create FTP server

To create a new FTP server if an existing FTP server is not available, perform the following steps:

1. From **AWS Management Console**, navigate to **EC2 > Instances > <FTP_server_name>**.
2. Click **Launch Instances**.
A **Launch an instance** window is displayed.
3. In the **Name and tags** section, enter an instance name.
Here, enter `FTPserver` as the FTP server instance name.
4. In the **Application and OS Images** section, select **Ubuntu**.
5. In the **Instance type** section, select the required instance type.
6. In the **Key pair (login)** field, select your SSH key.
7. In the **Network settings** section, click **Edit** to edit the following:
 - VPC: *your VPC*
Here, enter `vpc` as the VPC.
 - Subnet: Data subnet
Here, `10.0.3.0/24` is the data subnet value.

- Auto-assign public IP: Enable
 - Firewall (security groups): Select existing security group
 - Common security groups: *your data security group*
Here, `vpc-vThunderSecurityGroupData` is the security group.
8. Click **Launch instance**.

NOTE: The system may take a few minutes to launch the instance.

The FTP server instance is displayed in the **Instances** list with the status as **Running**.

9. Click **Connect**.
A **Connect to instance** window with **EC2 Instance Connect** tab is displayed.
10. Click **Connect**.
A **Terminal** window is displayed.

Configure FTP server

To configure a new or existing FTP server, perform the following steps:

1. Run the following command in the Terminal window of the FTP server instance to update all the package information:

```
sudo apt update
```

2. Run the following command to create an Apache Server virtual machine:

```
sudo apt install apache2
```

While the Apache server is getting installed, you get a prompt to continue further. Enter 'Y' to continue. After the installation is complete, a newline prompt is displayed.

3. Run the following command to open the `aws_access_key.txt` file:

```
sudo vi /var/www/html/aws_access_key.txt
```

4. Press **Esc** and enter **i** to enable edit/insert mode.
5. Locate and open the **credentials** file from downloaded CFT folder.

6. Copy the updated access key ID and secret access key as per your AWS account and paste in the `aws_access_key.txt` file. For more information, see [Prerequisites](#).
7. After the changes, press **Esc** then type **:wq** to save the changes and exit.

The AWS access keys are imported.

NOTE: The FTP server should be deleted manually after the AWS access keys are imported to the vThunder instance.

Delete the resources

In case you want to delete the auto scaling group, you should also delete the Lambda Function and S3 bucket manually.

Lambda Function

To delete the Lambda Function, perform the following steps:

1. From **AWS Management Console**, navigate to **Lambda > Functions** and select the required lambda function.
2. Click **Action > Delete**.
3. Provide the confirmation in the input field and click **Delete**.

The Lambda Function is deleted.

S3 Bucket

Before deleting your S3 Bucket, make sure the bucket is empty. To delete the S3 Bucket, perform the following steps:

1. From **AWS Management Console**, navigate to **Amazon S3 > Buckets** and select the required bucket name from the list.
2. Click **Empty**.
3. Confirm the bucket name that you want to empty in the text field of the **Empty**

bucket window, and then click **Empty**.

4. Select the same bucket name from the list in the **Buckets** window and click **Delete**.
5. Confirm the bucket name that you want to delete in the text field of the **Delete bucket** window, and then click **Delete**.

The S3 Bucket is deleted.

Install Python3

Depending on your operating system, install Python (3.8.5 or higher):

CentOS

To install latest Python3 from OS repository on CentOS, perform the following steps:

```
yum install -y python3
```

Linux/Ubuntu

To install Python3 on Linux or Ubuntu, perform the following steps:

```
apt update  
apt-get install python3.10  
apt install python3-pip
```

Windows

To install Python3 on Windows, see [Using Python on Windows](#).

Verify Installation

To verify if the recommended Python version is installed correctly, perform the following steps:

1. Run the following command using the command prompt:

CentOS/Linux/Ubuntu

```
$ python3 --version
```

Windows

```
$ python--version
```

If Python is installed, the version details are displayed. Ensure that the version is 3.8.5 or higher.

2. Run the following command to verify if PIP is installed.

```
$ pip
```

If PIP is installed, the `pip` command usage, commands and other general options are displayed.

Install Python dependencies

To install all Python dependencies, perform the following steps:

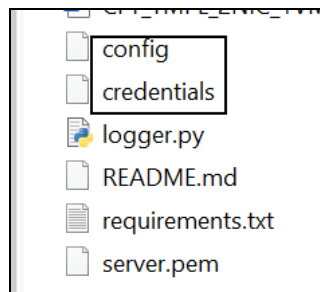

- a. From the command prompt, navigate to the downloaded CFT folder path and enter the following command:

```
$ pip install -r requirements.txt
```

A `.aws` folder is automatically created under `C:\Users\TestUser`.

- b. From the downloaded CFT folder, locate and open the **credentials** file with a text editor.

Figure 55 : CFT folder

- c. Update the access key ID and secret access key as per your AWS account and then save the changes.

```
[default]
aws_access_key_id = your_aws_access_key_id
aws_secret_access_key = your_aws_secret_access_key
```

- d. Copy this file to the C:\Users\TestUser\.aws folder.
- e. From the downloaded CFT template folder, locate and open the **config** file with a text editor.
- f. Update region with your working region and then save the changes.

```
[default]
region = you_working_region
output = json
```

- g. Copy this file to the C:\Users\TestUser\.aws folder.

List of ACOS AMI ID

The following table lists the available ACOS AMI ID in the AWS cloud:

ACOS Image name	AMI IDs Region-wise	
	Region	AMI ID
A10 Thunder ADC for Advanced Load Balancing - 20 Mbps	US East (N. Virginia) - us-east-1	ami-00fbb189ff839e3f8

Security Policy for AWS User

To deploy the vThunder instance using a CFT template, an AWS user requires certain security policies. The following security policies are recommended:

Predefined

- AmazonEC2FullAccess
- AmazonS3FullAccess
- AmazonS3ObjectLambdaExecutionRolePolicy
- AmazonVPCFullAccess

Custom

- Create and Edit Secrets

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "secretsmanager:CreateSecret",
        "secretsmanager:PutSecretValue"
      ],
      "Resource": "arn:aws:secretsmanager:us-east-1:939850196882:secret:*"
    }
  ]
}
```

- Lambda Update

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "ConfigureFunctions",
      "Effect": "Allow",
      "Action": [
        "lambda:UpdateFunctionConfiguration",
        "lambda:GetFunction"
      ],
      "Resource": "*",
      "Condition": {
        "ForAllValues:StringLike": {
          "lambda:Layer": [
            "arn:aws:lambda:*:939850196882:layer:*:*"

Supported Instance Types

[Table 32](#) provides detailed information about the supported instance types.

Table 32 : List of Supported Instance Types

Instance	vCPU	Memory	Number of Network Interfaces
c4.xlarge	4	7680	4
c4.4xlarge	16	30720	8
c4.8xlarge	36	61440	8
d2.xlarge	4	31232	4
d2.2xlarge	8	62464	4

Instance	vCPU	Memory	Number of Network Interfaces
d2.4xlarge	16	124928	8
d2.8xlarge	36	249856	8
m4.xlarge	4	16384	4
m4.2xlarge	8	32768	4
m4.4xlarge	16	65536	8
m4.10xlarge	40	163840	8
i2.xlarge	4	31232	4
i2.2xlarge	8	62464	4
i2.4xlarge	16	124928	8
i2.8xlarge	32	249856	8
c5d.large	2	4096	3
c5d.9xlarge	36	73728	8
c5d.2xlarge	8	32768	4
c5d.4xlarge	16	73728	8
c5.xlarge	4	8192	4
c5.2xlarge	8	16384	4
c5.4xlarge	16	32768	8
c5.9xlarge	36	73728	8
g3.4xlarge	16	124928	8
g3.8xlarge	32	249856	8
i3.large	2	15616	3
i3.xlarge	4	31232	4
i3.2xlarge	8	62464	4
i3.4xlarge	16	124928	8
i3.8xlarge	32	249856	8
m5d.large	2	8192	3
m5d.xlarge	4	16384	4
m5d.2xlarge	8	32768	4

Instance	vCPU	Memory	Number of Network Interfaces
m5d.4xlarge	16	65536	8
m5.large	2	8192	3
m5.xlarge	4	16384	4
m5.2xlarge	8	32768	4
m5.4xlarge	16	65536	8
r5d.large	2	16384	3
r5d.xlarge	4	32768	4
r5d.2xlarge	8	65536	4
r5d.4xlarge	16	131072	8
r5.large	2	16384	3
r5.xlarge	4	32768	4
r5.2xlarge	8	65536	4
r5.4xlarge	16	131072	8
r4.large	2	15616	3
r4.xlarge	4	31232	4
r4.2xlarge	8	62464	4
r4.4xlarge	16	124928	8
r4.8xlarge	32	249856	8
t3.medium	2	4096	3

Support Information

For any issues or queries related to CFT templates, open a case at [A10 Networks Support](#) or reach out to support@a10networks.com and mention "A10-AWS-CFT-templates" in the subject line.

What's New

1.3.0

This release has the following enhancements for Thunder® Application Delivery Controller (ADC):

- Added a template for creating new virtual private cloud (VPC) containing six new subnets and two new security groups (SGs) in same or different availability zone in the same region.
- Added a template for deploying two vThunder instances in the same or different availability zones, including resources such as three network interface cards, Private IPs (Alien IPs), and Elastic IPs.
- Added new HA Across AZs configuration to enable high availability across availability zones.

1.2.0

This release has the following enhancements for Thunder® Application Delivery Controller (ADC):

- Added support for ACOS 6.0.2, ACOS 6.0.1, and ACOS 5.2.1-P8.
- Added a template for creating new virtual private cloud (VPC) containing three new subnets and two new security groups (SGs).
- Added a template for creating new elastic public IP addresses.
- Separated the deployment and configuration parameters to ensure a clear distinction between the resources needed for initial deployment and those required for subsequent configuration and customization.
- Introduced two new SLB templates, SLB HTTP and Persist Cookie to enhance the functionality and performance of the Server Load Balancer (SLB) by optimizing HTTP traffic distribution and implementing efficient cookie persistence.

- Added new hybrid cloud GSLB configuration to optimize performance, reliability, and ease of use in hybrid cloud environments.

1.1.0

This release has the following enhancements for Thunder® Application Delivery Controller (ADC):

- Added support for ACOS 5.2.1-P7, ACOS 6.0.0-P1, and ACOS 6.0.0-P2.
- Added Thunder password change capability.

1.0.0

This release has the following enhancements for Thunder® Application Delivery Controller (ADC):

- Added support for ACOS 5.2.1-P6.
- Added GLM, HA, SLB, and SSL vThunder configuration.
- Added the following deployment templates:
 - A10-vThunder_ADC-2NIC-1VM-GLM
 - A10-vThunder_ADC-2NIC-1VM
 - A10-vThunder_ADC-3NIC-2VM-HA-GLM-PUBVIP-BACKAUTO
 - A10-vThunder_ADC-3NIC-2VM-HA-GLM-PVTVIP
 - A10-vThunder_ADC-3NIC-2VM-HA
 - A10-vThunder_ADC-3NIC-6VM-2RG-GSLB
 - A10-vThunder_ADC-3NIC-VMSS
